SONiX 8-Bit Micro-Controller

SONIX reserves the right to make change without further notice to any products herein to improve reliability, function or design. SONIX does not assume any liability arising out of the application or use of any product or circuit described herein; neither does it convey any license under its patent rights nor the rights of others. SONIX products are not designed, intended, or authorized for us as components in systems intended, for surgical implant into the body, or other applications intended to support or sustain life, or for any other application in which the failure of the SONIX product could create a situation where personal injury or death may occur. Should Buyer purchase or use SONIX products for any such unintended or unauthorized application. Buyer shall indemnify and hold SONIX and its officers, employees, subsidiaries, affiliates and distributors harmless against all claims, cost, damages, and expenses, and reasonable attorney fees arising out of, directly or indirectly, any claim of personal injury or death associated with such unintended or unauthorized use even if such claim alleges that SONIX was negligent regarding the design or manufacture of the part.

AMENDENT HISTORY

Version	Date	Description			
VER 0.1	May. 2010	Preliminary first issue.			
VER 1.0	Apr. 2012	Add SN8P25231 part number.			
	-	2. Modify comparator de-bounce configuration.			
		3. Modify SN8P2523 EV-Kit section.			
		. Modify "DEVELOPMENT TOOL" description.			
		5. Add "Chapter 2.5" LVD_MAX code option description.			
		6. Modify "Chapter 13.3 CHARACTERISTIC GRAPHS"			
		7. Replace SSOP28 to SSOP24 package type.

PRODUCT OVERVIEW

1.1 FEATURES

- Memory configuration ROM size: 2K * 16 bits. RAM size: 256 * 8 bits.
- 8 levels stack buffer.
- 6 interrupt sources
 5 internal interrupts: T0, TC1, CM0, SIO, MSP
 1 external interrupt: INT0
- I/O pin configuration Bi-directional: P0, P1, P5. Wakeup: P0, P1 level change. Pull-up resisters: P0, P1, P5.
 - Programmable open-drain: P5.0~P5.2 Comparator input pin: CM0N0~CM0N11. Comparator output pin: CM0O.
- Fcpu (Instruction cycle)
 Fcpu = Fpsc/1, Fpsc/2, Fosc/4, Fosc/8, Fosc/16.
- Powerful instructions
 Instruction's length is one word.
 Most of instructions are one cycle only.
 All ROM area JMP/CALL instruction.
 All ROM area lookup table function (MOVC).

- One 8-bit basic timer. (T0).
- One 8-bit timer with duty/cycle programmable PWM. (TC1).
- 8-ch LED PWM driver.
- ♦ 12-channel comparator.
- SIO serial input/output interface.
- MSP slave mode interface.
- On chip watchdog timer and clock source is Internal low clock RC type (16KHz @3V, 32KHz @5V).
- Two system clocks
 Internal high clock: RC type 16MHz
 Internal low clock: RC type 16KHz(3V), 32KHz(5V)
- Four operating modes
 Normal mode: Both high and low clock active Slow mode: Low clock only
 Sleep mode: Both high and low clock stop Green mode: Periodical wakeup by timer
- Package (Chip form support)

1.4 PIN DESCRIPTIONS

PIN NAME	TYPE	DESCRIPTION
VDD, VSS	Р	Power supply input pins.
		RST: System reset input pin. Schmitt trigger structure, low active, normal stay to "high".
P0.5/RST/VPP	I, P	VPP: OTP 12.3V power input pin in programming mode.
FU.3/K31/VFF	I, F	P0.5: Input only pin. Schmitt trigger structure. Built-in wakeup function.
		The external reset function must be disabled.
		Port 0.0 bi-direction pin. Schmitt trigger structure as input mode.
P0.0/INT0/CM0O	I/O	Built-in pull-up resisters and wakeup function.
F0.0/INT0/CIVIOC	1/0	INT0 trigger pin (Schmitt trigger).
		CM0O: The output pin of comparator.
		P0.1-0.4 bi-direction pin. Schmitt trigger structure as input mode.
P0[4:1]/ LPW[3:0]	I/O	Built-in pull-up resisters and wakeup function.
		LPW[3:0]: LED[3:0] PWM output pin.
		Port 1 bi-direction pin. Schmitt trigger structure as input mode.
P1[7:0]/CM0N[7:0]	I/O	Built-in pull-up resisters and wakeup function.
		CM0N[7:0]: Channel 0~7 of comparator negative input pin.
		Port 5.0 bi-direction pin. Schmitt trigger structure as input mode.
P5.0/SCK/SCL	I/O	Built-in pull-up resisters. Programmable open-drain.
F5.0/30N/30L	1/0	SCK: SIO clock pin.
		SCL: MSP clock pin
		Port 5.1 bi-direction pin. Schmitt trigger structure as input mode.
P5.1/SI/SDA	I/O	Built-in pull-up resisters. Programmable open-drain.
F 5. 1/51/5DA	1/0	SI: SIO data input pin.
		SDA: MSP data pin
		Port 5.2 bi-direction pin. Schmitt trigger structure as input mode.
P5.2/SO	I/O	Built-in pull-up resisters. Programmable open-drain.
		SO: SIO data output pin.
		Port 5.3 bi-direction pin. Schmitt trigger structure as input mode.
P5.3/PWM1/CMSO	I/O	Built-in pull-up resisters.
F 5.5/F WWWI/CWISO	1/0	PWM1: PWM output pin.
		CMSO: Compensation output pin.
		Port 5.4-5.7 bi-direction pin. Schmitt trigger structure as input mode.
P5[7:4]/CM0N[11:8]/	I/O	Built-in pull-up resisters.
LPW[7:4]	1/0	CM0N[11:8]: Channel 8~11 of comparator negative input pin.
		LPW[7:4]: LED[7:4] PWM output pin.

2 CENTRAL PROCESSOR UNIT (CPU)

2.1 PROGRAM MEMORY (ROM)

2K words ROM

The ROM includes Reset vector, Interrupt vector, General purpose area and Reserved area. The Reset vector is program beginning address. The Interrupt vector is the head of interrupt service routine when any interrupt occurring. The General purpose area is main program area including main loop, sub-routines and data table.

START:

2.1.1 RESET VECTOR (0000H)

A one-word vector address area is used to execute system reset.

- Power On Reset (NT0=1, NPD=0).
- Watchdog Reset (NT0=0, NPD=0).
- External Reset (NT0=1, NPD=1).

After power on reset, external reset or watchdog timer overflow reset, then the chip will restart the program from address 0000h and all system registers will be set as default values. It is easy to know reset status from NT0, NPD flags of PFLAG register. The following example shows the way to define the reset vector in the program memory.

> Example: Defining Reset Vector

ORG JMP	0 Start	; 0000H ; Jump to user program address.
ORG 	10H	; 0010H, The head of user program. ; User program
ENDP		; End of program

2.1.2 INTERRUPT VECTOR (0008H)

A 1-word vector address area is used to execute interrupt request. If any interrupt service executes, the program counter (PC) value is stored in stack buffer and jump to 0008h of program memory to execute the vectored interrupt. Users have to define the interrupt vector. The following example shows the way to define the interrupt vector in the program memory.

 Note: "PUSH", "POP" instructions save and load ACC/PFLAG without (NT0, NPD). PUSH/POP buffer is a unique buffer and only one level.

> Example: Defining Interrupt Vector. The interrupt service routine is following ORG 8.

.CODE	ORG JMP 	0 START	; 0000H ; Jump to user program address.
	ORG PUSH	8	; Interrupt vector. ; Save ACC and PFLAG register to buffers.
	POP RETI		; Load ACC and PFLAG register from buffers. ; End of interrupt service routine
START:			; The head of user program. ; User program
	 JMP 	START	; End of user program
	ENDP		; End of program

> Example: Defining Interrupt Vector. The interrupt service routine is following user program.

.CODE	ORG JMP	0 START	; 0000H ; Jump to user program address.
	ORG JMP	8 MY_IRQ	; Interrupt vector. ; 0008H, Jump to interrupt service routine address.
START:	ORG 	10H	; 0010H, The head of user program. ; User program.
	JMP	START	; End of user program.
MY_IRQ:	PUSH		;The head of interrupt service routine. ; Save ACC and PFLAG register to buffers.
	POP RETI		; Load ACC and PFLAG register from buffers. ; End of interrupt service routine.
	ENDP		; End of program.

* Note: It is easy to understand the rules of SONIX program from demo programs given above. These points are as following:

1. The address 0000H is a "JMP" instruction to make the program starts from the beginning.

2. The address 0008H is interrupt vector.

3. User's program is a loop routine for main purpose application.

2.1.3 LOOK-UP TABLE DESCRIPTION

In the ROM's data lookup function, Y register is pointed to middle byte address (bit 8~bit 15) and Z register is pointed to low byte address (bit 0~bit 7) of ROM. After MOVC instruction executed, the low-byte data will be stored in ACC and high-byte data stored in R register.

> Example: To look up the ROM data located "TABLE1".

	B0MOV B0MOV MOVC	Y, #TABLE1\$M Z, #TABLE1\$L	; To set lookup table1's middle address ; To set lookup table1's low address. ; To lookup data, R = 00H, ACC = 35H					
	INCMS Z JMP @F INCMS Y NOP		; Increment the index address for next address. ; Z+1 ; Z is not overflow. ; Z overflow (FFH → 00), → Y=Y+1 ;					
@@:	MOVC		; ; To lookup data, R = 51H, ACC = 05H.					
TABLE1:	DW DW DW	0035H 5105H 2012H	; ; To define a word (16 bits) data.					

Note: The Y register will not increase automatically when Z register crosses boundary from 0xFF to 0x00. Therefore, user must be take care such situation to avoid look-up table errors. If Z register is overflow, Y register must be added one. The following INC_YZ macro shows a simple method to process Y and Z registers automatically.

Example: INC_YZ macro.

INC_YZ	MACRO INCMS JMP	Z @F	; Z+1 ; Not overflow
@ @·	INCMS NOP	Y	; Y+1 ; Not overflow
@@:	ENDM		

> Example: Modify above example by "INC_YZ" macro.

	B0MOV B0MOV MOVC	Y, #TABLE1\$M Z, #TABLE1\$L	; To set lookup table1's middle address ; To set lookup table1's low address. ; To lookup data, R = 00H, ACC = 35H					
	INC_YZ		; Increment the index address for next address.					
@@:	MOVC		, ; To lookup data, R = 51H, ACC = 05H.					
TABLE1:	DW DW DW	0035H 5105H 2012H	, ; To define a word (16 bits) data.					

The other example of look-up table is to add Y or Z index register by accumulator. Please be careful if "carry" happen.

> Example: Increase Y and Z register by B0ADD/ADD instruction.

	B0MOV B0MOV	Y, #TABLE1\$M Z, #TABLE1\$L	; To set lookup table's middle address. ; To set lookup table's low address.
	B0MOV B0ADD	A, BUF Z, A	; Z = Z + BUF.
	B0BTS1 JMP INCMS NOP	FC GETDATA Y	; Check the carry flag. ; FC = 0 ; FC = 1. Y+1.
GETDATA:	MOVC		; ; To lookup data. If BUF = 0, data is 0x0035 ; If BUF = 1, data is 0x5105 ; If BUF = 2, data is 0x2012
TABLE1:	DW DW DW	0035H 5105H 2012H	; To define a word (16 bits) data.

2.1.4 JUMP TABLE DESCRIPTION

The jump table operation is one of multi-address jumping function. Add low-byte program counter (PCL) and ACC value to get one new PCL. If PCL is overflow after PCL+ACC, PCH adds one automatically. The new program counter (PC) points to a series jump instructions as a listing table. It is easy to make a multi-jump program depends on the value of the accumulator (A).

* Note: PCH only support PC up counting result and doesn't support PC down counting. When PCL is carry after PCL+ACC, PCH adds one automatically. If PCL borrow after PCL–ACC, PCH keeps value and not change.

> Example: Jump table.

ORG	0X0100	; The jump table is from the head of the ROM boundary
B0ADD	PCL, A	; PCL = PCL + ACC, PCH + 1 when PCL overflow occurs .
JMP	A0POINT	; ACC = 0, jump to A0POINT
JMP	A1POINT	; ACC = 1, jump to A1POINT
JMP	A2POINT	; ACC = 2, jump to A2POINT
JMP	A3POINT	; ACC = 3, jump to A3POINT

SONIX provides a macro for safe jump table function. This macro will check the ROM boundary and move the jump table to the right position automatically. The side effect of this macro maybe wastes some ROM size.

> Example: If "jump table" crosses over ROM boundary will cause errors.

@JMP_A	MACRO	VAL
	IF	((\$+1) !& 0XFF00) !!= ((\$+(VAL)) !& 0XFF00)
	JMP	(\$ 0XFF)
	ORG	(\$ 0XFF)
	ENDIF	
	B0ADD ENDM	PCL, A

Note: "VAL" is the number of the jump table listing number.

Example: "@JMP_A" application in SONIX macro file called "MACRO3.H".

BOMOV	A, BUF0	; "BUF0" is from 0 to 4.
@JMP_A	5	; The number of the jump table listing is five.
JMP	A0POINT	; ACC = 0, jump to A0POINT
JMP	A1POINT	; ACC = 1, jump to A1POINT
JMP	A2POINT	; ACC = 2, jump to A2POINT
JMP	A3POINT	; ACC = 3, jump to A3POINT
JMP	A4POINT	; $ACC = 4$, jump to A4POINT

If the jump table position is across a ROM boundary (0x00FF~0x0100), the "@JMP_A" macro will adjust the jump table routine begin from next RAM boundary (0x0100).

Example: "@JMP_A" operation.

; Before compiling program.

ROM address

	B0MOV	A, BUF0	; "BUF0" is from 0 to 4.
	@JMP_A	5	; The number of the jump table listing is five.
0X00FD	JMP	A0POINT	; ACC = 0, jump to A0POINT
0X00FE	JMP	A1POINT	; ACC = 1, jump to A1POINT
0X00FF	JMP	A2POINT	; ACC = 2, jump to A2POINT
0X0100	JMP	A3POINT	; ACC = 3, jump to A3POINT
0X0101	JMP	A4POINT	; ACC = 4, jump to A4POINT

; After compiling program.

ROM address

	B0MOV	A, BUF0	; "BUF0" is from 0 to 4.
	@JMP_A	5	; The number of the jump table listing is five.
0X0100	JMP	A0POINT	; ACC = 0, jump to A0POINT
0X0101	JMP	A1POINT	; ACC = 1, jump to A1POINT
0X0102	JMP	A2POINT	; ACC = 2, jump to A2POINT
0X0103	JMP	A3POINT	; ACC = 3, jump to A3POINT
0X0104	JMP	A4POINT	; ACC = 4, jump to A4POINT

2.1.5 CHECKSUM CALCULATION

The last ROM address are reserved area. User should avoid these addresses (last address) when calculate the Checksum value.

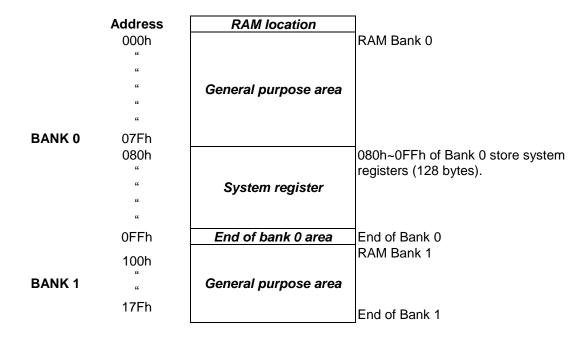

> Example: The demo program shows how to calculated Checksum from 00H to the end of user's code.

	MOV BOMOV MOV BOMOV CLR CLR	A,#END_USER_CODE\$L END_ADDR1, A A,#END_USER_CODE\$M END_ADDR2, A Y Z	; Save low end address to end_addr1 ; Save middle end address to end_addr2 ; Set Y to 00H ; Set Z to 00H
@@:	MOVC B0BCLR ADD MOV ADC JMP	FC DATA1, A A, R DATA2, A END_CHECK	; Clear C flag ; Add A to Data1 ; Add R to Data2 ; Check if the YZ address = the end of code
	INCMS JMP JMP	Z @B Y_ADD_1	; Z=Z+1 ; If Z != 00H calculate to next address ; If Z = 00H increase Y
END_CHECK:	MOV CMPRS JMP MOV CMPRS JMP JMP	A, END_ADDR1 A, Z AAA A, END_ADDR2 A, Y AAA CHECKSUM_END	; Check if Z = low end address ; If Not jump to checksum calculate ; If Yes, check if Y = middle end address ; If Not jump to checksum calculate ; If Yes checksum calculated is done.
Y_ADD_1:	INCMS NOP	Y	; Increase Y
CHECKSUM_END:	JMP	@B	; Jump to checksum calculate
END_USER_CODE:			; Label of program end

2.2.1.2 SYSTEM REGISTER DESCRIPTION

- H, L = Working, @HL.
- R = Working register and ROM look-up data buffer.
- CMOM = Comparator configuration register. SIOM = SIO configuration register.
- SIOB = SIO data buffer.
- PEDGE = P0.0 edge direction register. INTEN = Interrupt enable register.
- WDTR = Watchdog timer clear register.
 - Pn = Port n data buffer.
 - T0M = T0 mode register.
- TCOM = TC0 mode register.
- TC0Rn = TC0 pwm data buffer.
- TC1M = TC1 mode register.
- TC1R = TC1 auto-reload data buffer.
- @HL = RAM HL indirect addressing index pointer.
- STK0~STK7 = Stack 0 ~ stack 7 buffer.
 - MSPSTAT MSP status register
 - MSPBUF MSP buffer data

- Y, Z = Working, @YZ and ROM addressing register.
- PFLAG = ROM page and special flag register.
- CM0M1 = Comparator configuration register.
 - SIOR = SIO clock register.
 - PnM = Port n input/output mode register.
- INTRQ = Interrupt request register.
- OSCM = Oscillator mode register.
- PCH, PCL = Program counter.
 - PnUR = Port n pull-up resister control register.
 - TOC = TO counting register.
 - TC0C = TC0 counting register.
 - LPWS = PWM channel selection.
 - TC1C = TC1 counting register.
 - TC1D = TC1 duty control register.
 - @YZ = RAM YZ indirect addressing index pointer.
 - STKP = Stack pointer buffer.
 - MSPM1 MSP mode register1 MSPADR MSP address register

0FFH						S0PC10	S0PC9	S0PC8	R/W	STK0H

Note:

- 1. To avoid system error, make sure to put all the "0" and "1" as it indicates in the above table.
- 2. All of register names had been declared in SN8ASM assembler.
- 3. One-bit name had been declared in SN8ASM assembler with "F" prefix code.
- 4. "b0bset", "b0bclr", "bset", "bclr" instructions are only available to the "R/W" registers.

2.2.2 ACCUMULATOR

The ACC is an 8-bit data register responsible for transferring or manipulating data between ALU and data memory. If the result of operating is zero (Z) or there is carry (C or DC) occurrence, then these flags will be set to PFLAG register. ACC is not in data memory (RAM), so ACC can't be access by "B0MOV" instruction during the instant addressing mode.

> Example: Read and write ACC value.

; Read ACC data and store in BUF data memory.

MOV BUF, A

; Write a immediate data into ACC.

MOV A, #0FH

; Write ACC data from BUF data memory.

MOV A, BUF

B0MOV A, BUF

The system doesn't store ACC and PFLAG value when interrupt executed. ACC and PFLAG data must be saved to other data memories. "PUSH", "POP" save and load ACC, PFLAG data into buffers.

> Example: Protect ACC and working registers.

INT_SERVICE:

; or

PUSH	; Save ACC and PFLAG to buffers.
POP	; Load ACC and PFLAG from buffers.
RETI	; Exit interrupt service vector

2.2.3 PROGRAM FLAG

The PFLAG register contains the arithmetic status of ALU operation, system reset status and LVD detecting status. NT0, NPD bits indicate system reset status including power on reset, LVD reset, reset by external pin active and watchdog reset. C, DC, Z bits indicate the result status of ALU operation. LVD24, LVD36 bits indicate LVD detecting power voltage status.

086H	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
PFLAG	NT0	NPD	LVD36	LVD24	-	С	DC	Z
Read/Write	R/W	R/W	R	R	-	R/W	R/W	R/W
After reset	-	-	0	0	-	0	0	0

Bit [7:6] NT0, NPD: Reset status flag.

NT0	NPD	Reset Status
0	0	Watch-dog time out
0	1	Reserved
1	0	Reset by LVD
1	1	Reset by external Reset Pin

Bit 5 **LVD36:** LVD 3.6V operating flag and only support LVD code option is LVD_H.

- 0 =Inactive (VDD > 3.6V).
- $1 = \text{Active (VDD } \leq 3.6\text{V}).$
- Bit 4 LVD24: LVD 2.4V operating flag and only support LVD code option is LVD_M.
 - 0 =Inactive (VDD > 2.4V).
 - 1 = Active (VDD ≤ 2.4 V).

Bit 2 C: Carry flag

- 1 = Addition with carry, subtraction without borrowing, rotation with shifting out logic "1", comparison result ≥ 0 .
- 0 = Addition without carry, subtraction with borrowing signal, rotation with shifting out logic "0", comparison result < 0.

Bit 1 DC: Decimal carry flag

- 1 = Addition with carry from low nibble, subtraction without borrow from high nibble.
- 0 = Addition without carry from low nibble, subtraction with borrow from high nibble.

Bit 0 Z: Zero flag

- 1 = The result of an arithmetic/logic/branch operation is zero.
- 0 = The result of an arithmetic/logic/branch operation is not zero.

* Note: Refer to instruction set table for detailed information of C, DC and Z flags.

2.2.4 PROGRAM COUNTER

The program counter (PC) is a 11-bit binary counter separated into the high-byte 3 and the low-byte 8 bits. This counter is responsible for pointing a location in order to fetch an instruction for kernel circuit. Normally, the program counter is automatically incremented with each instruction during program execution.

Besides, it can be replaced with specific address by executing CALL or JMP instruction. When JMP or CALL instruction is executed, the destination address will be inserted to bit 0 ~ bit 10.

	Bit 15	Bit 14	Bit 13	Bit 12	Bit 11	Bit 10	Bit 9	Bit 8	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
PC	-	-	-	-	-	PC10	PC9	PC8	PC7	PC6	PC5	PC4	PC3	PC2	PC1	PC0
After reset	-	-	-	-	-	0	0	0	0	0	0	0	0	0	0	0
		PCH								P	CL					

ONE ADDRESS SKIPPING

There are nine instructions (CMPRS, INCS, INCMS, DECS, DECMS, BTS0, BTS1, B0BTS0, B0BTS1) with one address skipping function. If the result of these instructions is true, the PC will add 2 steps to skip next instruction.

If the condition of bit test instruction is true, the PC will add 2 steps to skip next instruction.

COSTEP:	B0BTS1 JMP NOP	FC COSTEP	; To skip, if Carry_flag = 1 ; Else jump to C0STEP.
	B0MOV B0BTS0 JMP	A, BUF0 FZ C1STEP	; Move BUF0 value to ACC. ; To skip, if Zero flag = 0. ; Else jump to C1STEP.
C1STEP:	NOP		

If the ACC is equal to the immediate data or memory, the PC will add 2 steps to skip next instruction.

	CMPRS	A, #12H	; To skip, if ACC = 12H.
	JMP	COSTEP	; Else jump to C0STEP.
COSTEP:	 NOP		

If the destination increased by 1, which results overflow of 0xFF to 0x00, the PC will add 2 steps to skip next instruction.

INCS instruction:	INCS JMP 	BUF0 COSTEP	; Jump to C0STEP if ACC is not zero.
COSTEP:	 NOP		
INCMS instruction:	INCMS JMP NOP	BUF0 COSTEP	; Jump to C0STEP if BUF0 is not zero.

If the destination decreased by 1, which results underflow of 0x01 to 0x00, the PC will add 2 steps to skip next instruction.

DECS instruction:			
	DECS JMP	BUF0 C0STEP	; Jump to COSTEP if ACC is not zero.
C0STEP:	NOP		

DECMS instruction:

	DECMS JMP	BUF0 C0STEP	; Jump to C0STEP if BUF0 is not zero.
COSTEP:	 NOP		

MULTI-ADDRESS JUMPING

Users can jump around the multi-address by either JMP instruction or ADD M, A instruction (M = PCL) to activate multi-address jumping function. Program Counter supports "ADD M,A", "ADC M,A" and "B0ADD M,A" instructions for carry to PCH when PCL overflow automatically. For jump table or others applications, users can calculate PC value by the three instructions and don't care PCL overflow problem.

* Note: PCH only support PC up counting result and doesn't support PC down counting. When PCL is carry after PCL+ACC, PCH adds one automatically. If PCL borrow after PCL–ACC, PCH keeps value and not change.

> Example: If PC = 0323H (PCH = 03H, PCL = 23H)

; PC = 0323H	MOV B0MOV 	A, #28H PCL, A	; Jump to address 0328H
; PC = 0328H	MOV B0MOV 	A, #00H PCL, A	; Jump to address 0300H

> Example: If PC = 0323H (PCH = 03H, PCL = 23H)

; PC = 0323H

B0ADD	PCL, A	; PCL = PCL + ACC, the PCH cannot be changed.
JMP	A0POINT	; If ACC = 0, jump to A0POINT
JMP	A1POINT	; ACC = 1, jump to A1POINT
JMP	A2POINT	; ACC = 2, jump to A2POINT
JMP	A3POINT	; ACC = 3, jump to A3POINT

2.2.5 H, L REGISTERS

The H and L registers are the 8-bit buffers. There are two major functions of these registers.

- Can be used as general working registers
- Can be used as RAM data pointers with @HL register

081H	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
Н	HBIT7	HBIT6	HBIT5	HBIT4	HBIT3	HBIT2	HBIT1	HBIT0
Read/Write	R/W							
After reset	-	-	-	-	-	-	-	-

080H	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
L	LBIT7	LBIT6	LBIT5	LBIT4	LBIT3	LBIT2	LBIT1	LBIT0
Read/Write	R/W							
After reset	-	-	-	-	-	-	-	-

Example: If want to read a data from RAM address 20H of bank_0, it can use indirectly addressing mode to access data as following.

B0MOV	H, #00H	; To set RAM bank 0 for H register
B0MOV	L, #20H	; To set location 20H for L register
B0MOV	A, @HL	; To read a data into ACC

> Example: Clear general-purpose data memory area of bank 0 using @HL register.

CLR_HL_BUF:	CLR	H	; H = 0, bank 0
	B0MOV	L, #07FH	; L = 7FH, the last address of the data memory area
	CLR	@HL	; Clear @HL to be zero
	DECMS	L	; L – 1, if L = 0, finish the routine
	JMP	CLR_HL_BUF	; Not zero
END_CLR:	CLR 	@HL	; End of clear general purpose data memory area of bank 0

2.2.6 Y, Z REGISTERS

The Y and Z registers are the 8-bit buffers. There are three major functions of these registers.

- Can be used as general working registers
- Can be used as RAM data pointers with @YZ register
- Can be used as ROM data pointer with the MOVC instruction for look-up table

084H	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
Y Y	YBIT7	YBIT6	YBIT5	YBIT4	YBIT3	YBIT2	YBIT1	YBIT0
Read/Write	R/W							
After reset	-	-	-	-	-	-	-	-

083H	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
Z	ZBIT7	ZBIT6	ZBIT5	ZBIT4	ZBIT3	ZBIT2	ZBIT1	ZBIT0
Read/Write	R/W							
After reset	-	-	-	-	-	-	-	-

Example: Uses Y, Z register as the data pointer to access data in the RAM address 025H of bank0.

B0MOV	Y, #00H	; To set RAM bank 0 for Y register
B0MOV B0MOV	Z, #25H A. @YZ	; To set location 25H for Z register ; To read a data into ACC
DOING	<i>N</i> , C	

Example: Uses the Y, Z register as data pointer to clear the RAM data.

	B0MOV	Y, #0	; Y = 0, bank 0
	B0MOV	Z, #07FH	; Z = 7FH, the last address of the data memory area
CLR_YZ_BUF:	CLR	@YZ	; Clear @YZ to be zero
	DECMS	Z	; Z – 1, if Z= 0, finish the routine
	JMP	CLR_YZ_BUF	; Not zero
END_CLR:	CLR	@YZ	; End of clear general purpose data memory area of bank (

2.2.7 R REGISTER

R register is an 8-bit buffer. There are two major functions of the register.

• Can be used as working register

 For store high-byte data of look-up table (MOVC instruction executed, the high-byte data of specified ROM address will be stored in R register and the low-byte data will be stored in ACC).

082H	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
R	RBIT7	RBIT6	RBIT5	RBIT4	RBIT3	RBIT2	RBIT1	RBIT0
Read/Write	R/W							
After reset	-	-	-	-	-	-	-	-

Note: Please refer to the "LOOK-UP TABLE DESCRIPTION" about R register look-up table application.

2.3 ADDRESSING MODE

2.3.1 IMMEDIATE ADDRESSING MODE

The immediate addressing mode uses an immediate data to set up the location in ACC or specific RAM.

\triangleright	Example: Mov	ve the immed	iate data 12H to A	CC.
		MOV	A, #12H	; To set an immediate data 12H into ACC.
	Example: Mov	ve the immed	iate data 12H to R	register.
		B0MOV	R, #12H	; To set an immediate data 12H into R register.
*	Note: In imme	diate addres	sing mode applica	ation, the specific RAM must be 0x80~0x87 working register.

2.3.2 DIRECTLY ADDRESSING MODE

The directly addressing mode moves the content of RAM location in or out of ACC.

Example: Move 0x12 RAM location data into ACC.

B0MOV A, 12H ; To get a content of RAM location 0x12 of bank 0 and save in ACC.

> Example: Move ACC data into 0x12 RAM location.

B0MOV 12H, A ; To get a content of ACC and save in RAM location 12H of bank 0.

2.3.3 INDIRECTLY ADDRESSING MODE

The indirectly addressing mode is to access the memory by the data pointer registers (H/L, Y/Z).

Example: Indirectly addressing mode with @HL register

B0MOV	H, #0	; To clear H register to access RAM bank 0.
B0MOV	L, #12H	; To set an immediate data 12H into L register.
B0MOV	A, @HL	; Use data pointer @HL reads a data from RAM location ; 012H into ACC.

> Example: Indirectly addressing mode with @YZ register

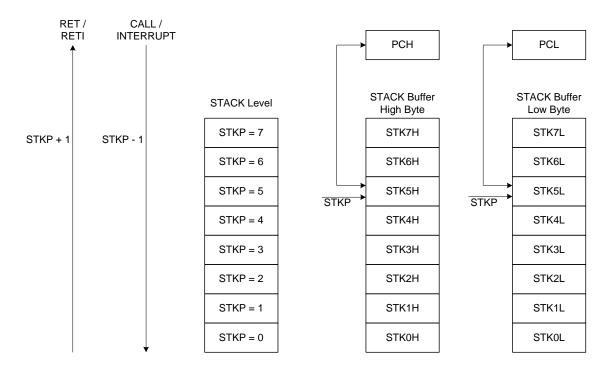

B0MOV	Y, #0	; To clear Y register to access RAM bank 0.
B0MOV	Z, #12H	; To set an immediate data 12H into Z register.
B0MOV	A, @YZ	; Use data pointer @YZ reads a data from RAM location
		; 012H into ACC.

2.4 STACK OPERATION

2.4.1 OVERVIEW

The stack buffer has 8-level. These buffers are designed to push and pop up program counter's (PC) data when interrupt service routine and "CALL" instruction are executed. The STKP register is a pointer designed to point active level in order to push or pop up data from stack buffer. The STKnH and STKnL are the stack buffers to store program counter (PC) data.

2.4.2 STACK REGISTERS

The stack pointer (STKP) is a 3-bit register to store the address used to access the stack buffer, 11-bit data memory (STKnH and STKnL) set aside for temporary storage of stack addresses.

The two stack operations are writing to the top of the stack (push) and reading from the top of stack (pop). Push operation decrements the STKP and the pop operation increments each time. That makes the STKP always point to the top address of stack buffer and write the last program counter value (PC) into the stack buffer.

The program counter (PC) value is stored in the stack buffer before a CALL instruction executed or during interrupt service routine. Stack operation is a LIFO type (Last in and first out). The stack pointer (STKP) and stack buffer (STKnH and STKnL) are located in the system register area bank 0.

0DFH	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
STKP	GIE	-	-	-	-	STKPB2	STKPB1	STKPB0

Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
After reset	0	0	0	0	0	0	0	0

STKn = STKnH, STKnL ($n = 7 \sim 0$)

2.4.3 STACK OPERATION EXAMPLE

The two kinds of Stack-Save operations refer to the stack pointer (STKP) and write the content of program counter (PC) to the stack buffer are CALL instruction and interrupt service. Under each condition, the STKP decreases and points to the next available stack location. The stack buffer stores the program counter about the op-code address. The Stack-Save operation is as the following table.

Stack Level	S	STKP Registe	er	Stack	Buffer	Decorintion	
Slack Level	STKPB2	STKPB1	STKPB0	High Byte	Low Byte	Description	
0	1	1	1	Free	Free	-	
1	1	1	0	STK0H	STK0L	-	
2	1	0	1	STK1H	STK1L	-	
3	1	0	0	STK2H	STK2L	-	
4	0	1	1	STK3H	STK3L	-	
5	0	1	0	STK4H	STK4L	-	
6	0	0	1	STK5H	STK5L	-	
7	0	0	0	STK6H	STK6L	-	
8	1	1	1	STK7H	STK7L	-	
> 8	1	1	0	-	-	Stack Over, error	

There are Stack-Restore operations correspond to each push operation to restore the program counter (PC). The RETI instruction uses for interrupt service routine. The RET instruction is for CALL instruction. When a pop operation occurs, the STKP is incremented and points to the next free stack location. The stack buffer restores the last program counter (PC) to the program counter registers. The Stack-Restore operation is as the following table.

Stack Level	S	STKP Registe	er	Stack	Buffer	Description	
Slack Level	STKPB2	STKPB1	STKPB0	High Byte	Low Byte	Description	
8	1	1	1	STK7H	STK7L	-	
7	0	0	0	STK6H	STK6L	-	
6	0	0	1	STK5H	STK5L	-	
5	0	1	0	STK4H	STK4L	-	
4	0	1	1	STK3H	STK3L	-	
3	1	0	0	STK2H	STK2L	-	
2	1	0	1	STK1H	STK1L	-	
1	1	1	0	STK0H	STK0L	-	
0	1	1	1	Free	Free	-	

2.5 CODE OPTION TABLE

The code option is the system hardware configurations including noise filter option, watchdog timer operation, LVD option, reset pin option and OTP ROM security control. The code option items are as following table:

Code Option	Content	Function Description			
	Always_On	Watchdog timer is always on enable even in power down and green mode.			
Watch_Dog	Enable	Enable watchdog timer. Watchdog timer stops in power down mode and green mode.			
	Disable	Disable Watchdog function.			
	Fhosc/1	Instruction cycle is 1 oscillator clocks.			
	Fhosc/2	Instruction cycle is 2 oscillator clocks.			
Fcpu	Fhosc/4	Instruction cycle is 4 oscillator clocks.			
	Fhosc/8	Instruction cycle is 8 oscillator clocks.			
	Fhosc/16	Instruction cycle is 16 oscillator clocks.			
Reset_Pin	Reset	Enable External reset pin.			
Resel_FIII	P05	Enable P0.5 input only without pull-up resister.			
Security	Enable	Enable ROM code Security function.			
Security	Disable	Disable ROM code Security function.			
	LVD_L	LVD will reset chip if VDD is below 2.0V			
	LVD_M	LVD will reset chip if VDD is below 2.0V			
LVD		Enable LVD24 bit of PFLAG register for 2.4V low voltage indicator.			
	LVD H	LVD will reset chip if VDD is below 2.4V			
		Enable LVD36 bit of PFLAG register for 3.6V low voltage indicator.			
	LVD_MAX	LVD will reset chip if VDD is below 3.6V			

2.5.1 Fcpu code option

Fcpu means instruction cycle of normal mode (high clock). In slow mode, the system clock source is internal low speed RC oscillator. The Fcpu of slow mode isn't controlled by Fcpu code option and fixed Flosc/4 (16KHz/4 @3V, 32KHz/4 @5V).

2.5.2 Reset_Pin code option

The reset pin is shared with general input only pin controlled by code option.

- **Reset:** The reset pin is external reset function. When falling edge trigger occurring, the system will be reset.
- **P05:** Set reset pin to general input only pin (P0.5). The external reset function is disabled and the pin is input pin.

2.5.3 Security code option

Security code option is OTP ROM protection. When enable security code option, the ROM code is secured and not dumped complete ROM contents.

3 RESET

3.1 OVERVIEW

The system would be reset in three conditions as following.

- Power on reset
- Watchdog reset
- Brown out reset
- External reset (only supports external reset pin enable situation)

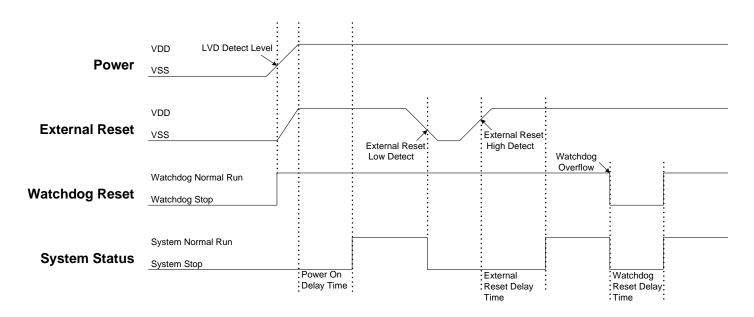

When any reset condition occurs, all system registers keep initial status, program stops and program counter is cleared. After reset status released, the system boots up and program starts to execute from ORG 0. The NT0, NPD flags indicate system reset status. The system can depend on NT0, NPD status and go to different paths by program.

086H	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
PFLAG	NT0	NPD	LVD36	LVD24	-	С	DC	Z
Read/Write	R/W	R/W	R	R	-	R/W	R/W	R/W
After reset	-	-	0	0	-	0	0	0

Bit [7:6] NT0, NPD: Reset status flag.

NT0	NPD	Condition	Description
0	0	Watchdog reset	Watchdog timer overflow.
0	1	Reserved	-
1	0	Power on reset and LVD reset.	Power voltage is lower than LVD detecting level.
1	1	External reset	External reset pin detect low level status.

Finishing any reset sequence needs some time. The system provides complete procedures to make the power on reset successful. For different oscillator types, the reset time is different. That causes the VDD rise rate and start-up time of different oscillator is not fixed. RC type oscillator's start-up time is very short, but the crystal type is longer. Under client terminal application, users have to take care the power on reset time for the master terminal requirement. The reset timing diagram is as following.

3.2 POWER ON RESET

The power on reset depend no LVD operation for most power-up situations. The power supplying to system is a rising curve and needs some time to achieve the normal voltage. Power on reset sequence is as following.

- **Power-up:** System detects the power voltage up and waits for power stable.
- External reset (only external reset pin enable): System checks external reset pin status. If external reset pin is not high level, the system keeps reset status and waits external reset pin released.
- **System initialization:** All system registers is set as initial conditions and system is ready.
- Oscillator warm up: Oscillator operation is successfully and supply to system clock.
- **Program executing:** Power on sequence is finished and program executes from ORG 0.

3.3 WATCHDOG RESET

Watchdog reset is a system protection. In normal condition, system works well and clears watchdog timer by program. Under error condition, system is in unknown situation and watchdog can't be clear by program before watchdog timer overflow. Watchdog timer overflow occurs and the system is reset. After watchdog reset, the system restarts and returns normal mode. Watchdog reset sequence is as following.

- Watchdog timer status: System checks watchdog timer overflow status. If watchdog timer overflow occurs, the system is reset.
- System initialization: All system registers is set as initial conditions and system is ready.
- Oscillator warm up: Oscillator operation is successfully and supply to system clock.
- **Program executing:** Power on sequence is finished and program executes from ORG 0.

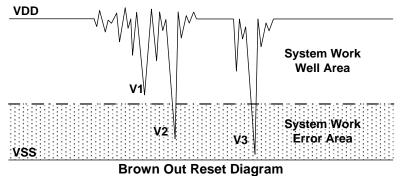

Watchdog timer application note is as following.

- Before clearing watchdog timer, check I/O status and check RAM contents can improve system error.
- Don't clear watchdog timer in interrupt vector and interrupt service routine. That can improve main routine fail.
- Clearing watchdog timer program is only at one part of the program. This way is the best structure to enhance the watchdog timer function.

Note: Please refer to the "WATCHDOG TIMER" about watchdog timer detail information.

3.4 BROWN OUT RESET

The brown out reset is a power dropping condition. The power drops from normal voltage to low voltage by external factors (e.g. EFT interference or external loading changed). The brown out reset would make the system not work well or executing program error.

The power dropping might through the voltage range that's the system dead-band. The dead-band means the power range can't offer the system minimum operation power requirement. The above diagram is a typical brown out reset diagram. There is a serious noise under the VDD, and VDD voltage drops very deep. There is a dotted line to separate the system working area. The above area is the system work well area. The below area is the system work error area called dead-band. V1 doesn't touch the below area and not effect the system operation. But the V2 and V3 is under the below area and may induce the system error occurrence. Let system under dead-band includes some conditions.

DC application:

The power source of DC application is usually using battery. When low battery condition and MCU drive any loading, the power drops and keeps in dead-band. Under the situation, the power won't drop deeper and not touch the system reset voltage. That makes the system under dead-band.

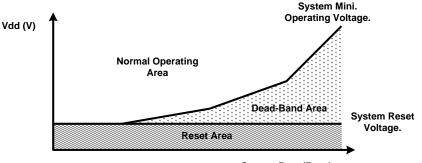

AC application:

In AC power application, the DC power is regulated from AC power source. This kind of power usually couples with AC noise that makes the DC power dirty. Or the external loading is very heavy, e.g. driving motor. The loading operating induces noise and overlaps with the DC power. VDD drops by the noise, and the system works under unstable power situation.

The power on duration and power down duration are longer in AC application. The system power on sequence protects the power on successful, but the power down situation is like DC low battery condition. When turn off the AC power, the VDD drops slowly and through the dead-band for a while.

3.5 THE SYSTEM OPERATING VOLTAGE

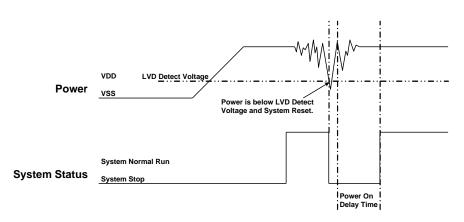

To improve the brown out reset needs to know the system minimum operating voltage which is depend on the system executing rate and power level. Different system executing rates have different system minimum operating voltage. The electrical characteristic section shows the system voltage to executing rate relationship.

System Rate (Fcpu)

Normally the system operation voltage area is higher than the system reset voltage to VDD, and the reset voltage is decided by LVD detect level. The system minimum operating voltage rises when the system executing rate upper even higher than system reset voltage. The dead-band definition is the system minimum operating voltage above the system reset voltage.

3.6 LOW VOLTAGE DETECTOR (LVD)

The LVD (low voltage detector) is built-in Sonix 8-bit MCU to be brown out reset protection. When the VDD drops and is below LVD detect voltage, the LVD would be triggered, and the system is reset. The LVD detect level is different by each MCU. The LVD voltage level is a point of voltage and not easy to cover all dead-band range. Using LVD to improve brown out reset is depend on application requirement and environment. If the power variation is very deep, violent and trigger the LVD, the LVD can be the protection. If the power variation can touch the LVD detect level and make system work error, the LVD can't be the protection and need to other reset methods. More detail LVD information is in the electrical characteristic section.

The LVD is three levels design (2.0V/2.4V/3.6V) and controlled by LVD code option. The 2.0V LVD is always enable for power on reset and Brown Out reset. The 2.4V LVD includes LVD reset function and flag function to indicate VDD status function. The 3.6V includes flag function to indicate VDD status. LVD flag function can be an **easy low battery detector**. LVD24, LVD36 flags indicate VDD voltage level. For low battery detect application, only checking LVD24, LVD36 status to be battery status. This is a cheap and easy solution.

086H	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
PFLAG	NT0	NPD	LVD36	LVD24	-	С	DC	Z
Read/Write	R/W	R/W	R	R	-	R/W	R/W	R/W
After reset	-	-	0	0	-	0	0	0

Bit 5 **LVD36:** LVD 3.6V operating flag and only support LVD code option is LVD_H.

0 = Inactive (VDD > 3.6V).

 $1 = \text{Active (VDD } \leq 3.6\text{V}).$

Bit 4 LVD24: LVD 2.4V operating flag and only support LVD code option is LVD_M.

0 = Inactive (VDD > 2.4V).

 $1 = \text{Active (VDD } \leq 2.4 \text{V}).$

LVD	LVD Code Option								
LVD	LVD_L	LVD_M	LVD_H	LVD_MAX					
2.0V Reset	Available	Available	Available	Available					
2.4V Flag	-	Available	-	-					
2.4V Reset	-	-	Available	Available					
3.6V Flag	-	-	Available	-					
3.6V Reset	-	-	-	Available					

LVD_L

If VDD < 2.0V, system will be reset.

Disable LVD24 and LVD36 bit of PFLAG register.

LVD_M

If VDD < 2.0V, system will be reset.

Enable LVD24 bit of PFLAG register. If VDD > 2.4V, LVD24 is "0". If VDD \leq 2.4V, LVD24 flag is "1". Disable LVD36 bit of PFLAG register.

LVD_H

If VDD < 2.4V, system will be reset.

Enable LVD36 bit of PFLAG register. If VDD > 3.6V, LVD36 is "0". If VDD ≦ 3.6V, LVD36 flag is "1".

LVD_MAX

If VDD < 3.6V, system will be reset.

* Note:

- 1. After any LVD reset, LVD24, LVD36 flags are cleared.
- 2. The voltage level of LVD 2.4V or 3.6V is for design reference only. Don't use the LVD indicator as precision VDD measurement.

3.7 BROWN OUT RESET IMPROVEMENT

How to improve the brown reset condition? There are some methods to improve brown out reset as following.

- LVD reset
- Watchdog reset
- Reduce the system executing rate
- External reset circuit. (Zener diode reset circuit, Voltage bias reset circuit, External reset IC)

* Note:

- 1. The "Zener diode reset circuit", "Voltage bias reset circuit" and "External reset IC" can completely improve the brown out reset, DC low battery and AC slow power down conditions.
- 2. For AC power application and enhance EFT performance, the system clock is 4MHz/4 (1 mips) and use external reset (" Zener diode reset circuit", "Voltage bias reset circuit", "External reset IC"). The structure can improve noise effective and get good EFT characteristic.

Watchdog reset:

following.

The watchdog timer is a protection to make sure the system executes well. Normally the watchdog timer would be clear at one point of program. Don't clear the watchdog timer in several addresses. The system executes normally and the watchdog won't reset system. When the system is under dead-band and the execution error, the watchdog timer can't be clear by program. The watchdog is continuously counting until overflow occurrence. The overflow signal of watchdog timer triggers the system to reset, and the system return to normal mode after reset sequence. This method also can improve brown out reset condition and make sure the system to return normal mode. If the system reset by watchdog and the power is still in dead-band, the system reset sequence won't be successful and the system stays in reset status until the power return to normal range. Watchdog timer application note is as

Reduce the system executing rate:

If the system rate is fast and the dead-band exists, to reduce the system executing rate can improve the dead-band. The lower system rate is with lower minimum operating voltage. Select the power voltage that's no dead-band issue and find out the mapping system rate. Adjust the system rate to the value and the system exits the dead-band issue. This way needs to modify whole program timing to fit the application requirement.

External reset circuit:

The external reset methods also can improve brown out reset and is the complete solution. There are three external reset circuits to improve brown out reset including "Zener diode reset circuit", "Voltage bias reset circuit" and "External reset IC". These three reset structures use external reset signal and control to make sure the MCU be reset under power dropping and under dead-band. The external reset information is described in the next section.

3.8 EXTERNAL RESET

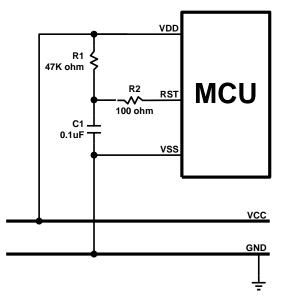

External reset function is controlled by "Reset_Pin" code option. Set the code option as "Reset" option to enable external reset function. External reset pin is Schmitt Trigger structure and low level active. The system is running when reset pin is high level voltage input. The reset pin receives the low voltage and the system is reset. The external reset operation actives in power on and normal running mode. During system power-up, the external reset pin must be high level input, or the system keeps in reset status. External reset sequence is as following.

- External reset (only external reset pin enable): System checks external reset pin status. If external reset pin is not high level, the system keeps reset status and waits external reset pin released.
- System initialization: All system registers is set as initial conditions and system is ready.
- Oscillator warm up: Oscillator operation is successfully and supply to system clock.
- **Program executing:** Power on sequence is finished and program executes from ORG 0.

The external reset can reset the system during power on duration, and good external reset circuit can protect the system to avoid working at unusual power condition, e.g. brown out reset in AC power application...

3.9 EXTERNAL RESET CIRCUIT

3.9.1 Simply RC Reset Circuit

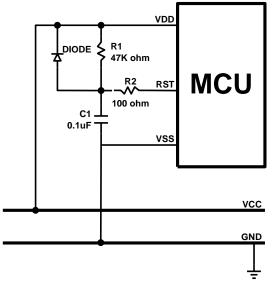

This is the basic reset circuit, and only includes R1 and C1. The RC circuit operation makes a slow rising signal into reset pin as power up. The reset signal is slower than VDD power up timing, and system occurs a power on signal from the timing difference.

Note: The reset circuit is no any protection against unusual power or brown out reset.

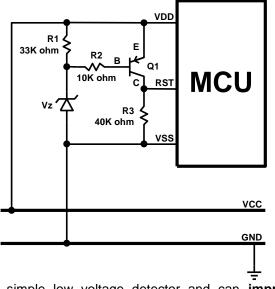

3.9.2 Diode & RC Reset Circuit

This is the better reset circuit. The R1 and C1 circuit operation is like the simply reset circuit to make a power on signal. The reset circuit has a simply protection against unusual power. The diode offers a power positive path to conduct higher power to VDD. It is can make reset pin voltage level to synchronize with VDD voltage. The structure can improve slight brown out reset condition.

 Note: The R2 100 ohm resistor of "Simply reset circuit" and "Diode & RC reset circuit" is necessary to limit any current flowing into reset pin from external capacitor C in the event of reset pin breakdown due to Electrostatic Discharge (ESD) or Electrical Over-stress (EOS).

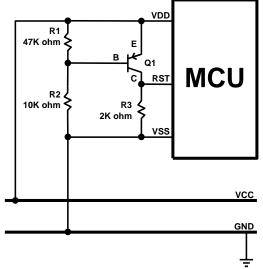

3.9.3 Zener Diode Reset Circuit

The zener diode reset circuit is a simple low voltage detector and can **improve brown out reset condition completely**. Use zener voltage to be the active level. When VDD voltage level is above "Vz + 0.7V", the C terminal of the PNP transistor outputs high voltage and MCU operates normally. When VDD is below "Vz + 0.7V", the C terminal of the PNP transistor outputs low voltage and MCU is in reset mode. Decide the reset detect voltage by zener specification. Select the right zener voltage to conform the application.

3.9.4 Voltage Bias Reset Circuit

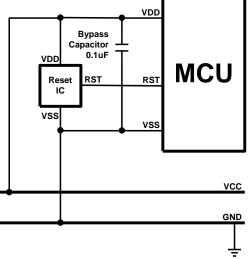

The voltage bias reset circuit is a low cost voltage detector and can **improve brown out reset condition completely**. The operating voltage is not accurate as zener diode reset circuit. Use R1, R2 bias voltage to be the active level. When VDD voltage level is above or equal to " $0.7V \times (R1 + R2) / R1$ ", the C terminal of the PNP transistor outputs high voltage and MCU operates normally. When VDD is below " $0.7V \times (R1 + R2) / R1$ ", the C terminal of the PNP transistor outputs low voltage and MCU is in reset mode.

Decide the reset detect voltage by R1, R2 resistances. Select the right R1, R2 value to conform the application. In the circuit diagram condition, the MCU's reset pin level varies with VDD voltage variation, and the differential voltage is 0.7V. If the VDD drops and the voltage lower than reset pin detect level, the system would be reset. If want to make the reset active earlier, set the R2 > R1 and the cap between VDD and C terminal voltage is larger than 0.7V. The external reset circuit is with a stable current through R1 and R2. For power consumption issue application, e.g. DC power system, the current must be considered to whole system power consumption.

Note: Under unstable power condition as brown out reset, "Zener diode rest circuit" and "Voltage bias reset circuit" can protects system no any error occurrence as power dropping. When power drops below the reset detect voltage, the system reset would be triggered, and then system executes reset sequence. That makes sure the system work well under unstable power situation.

3.9.5 External Reset IC

The external reset circuit also use external reset IC to enhance MCU reset performance. This is a high cost and good effect solution. By different application and system requirement to select suitable reset IC. The reset circuit can improve all power variation.

4 SYSTEM CLOCK

4.1 OVERVIEW

The micro-controller is a dual clock system including high-speed and low-speed clocks. The high-speed clock is internal high-speed oscillator. The low-speed clock is from internal low-speed oscillator controlled by "CLKMD" bit of OSCM register. Both high-speed clock and low-speed clock can be system clock source through a divider to decide the system clock rate.

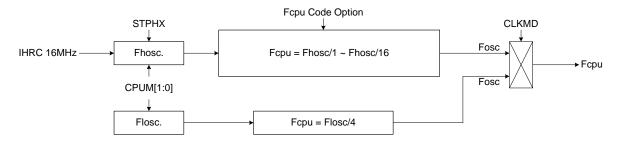

• High-speed oscillator

Internal high-speed oscillator is 16MHz RC type called "IHRC".

• Low-speed oscillator

Internal low-speed oscillator is 16KHz @3V, 32KHz @5V RC type called "ILRC".

• System clock block diagram

- Fhosc: Internal high-speed RC clock.
- Flosc: Internal low-speed RC clock (about 16KHz@3V, 32KHz@5V).
- Fosc: System clock source.
- Fcpu: Instruction cycle.

4.2 FCPU (INSTRUCTION CYCLE)

The system clock rate is instruction cycle called "**Fcpu**" which is divided from the system clock source and decides the system operating rate. Fcpu rate is selected by Fcpu code option and the range is **Fhosc/1~Fhosc/16** under system normal mode. If Fcpu code option is Fhosc/4, the Fcpu frequency is 16MHz/4 = 4MHz. Under system slow mode, the Fcpu is fixed Flosc/4, 16KHz/4=4KHz @3V, 32KHz/4=8KHz @5V.

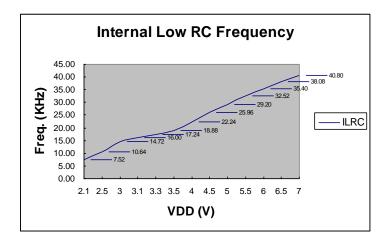

4.3 SYSTEM HIGH-SPEED CLOCK

The system high-speed clock is internal high-speed RC type oscillator and is the system clock source. The internal high-speed oscillator is 16MHz RC type. The accuracy is \pm 2% under commercial condition.

4.4 SYSTEM LOW-SPEED CLOCK

The system low clock source is the internal low-speed oscillator built in the micro-controller. The low-speed oscillator uses RC type oscillator circuit. The frequency is affected by the voltage and temperature of the system. In common condition, the frequency of the RC oscillator is about 16KHz at 3V and 32KHz at 5V. The relation between the RC frequency and voltage is as the following figure.

The internal low RC supports watchdog clock source and system slow mode controlled by "CLKMD" bit of OSCM register.

• Flosc = Internal low RC oscillator (about 16KHz @3V, 32KHz @5V).

• Slow mode Fcpu = Flosc / 4

There are two conditions to stop internal low RC. One is power down mode, and the other is green mode of 32K mode and watchdog disable. If system is in 32K mode and watchdog disable, only 32K oscillator actives and system is under low power consumption.

> Example: Stop internal low-speed oscillator by power down mode.

 B0BSET
 FCPUM0
 ; To stop external high-speed oscillator and internal low-speed

 ; oscillator called power down mode (sleep mode).
 ;

* Note: The internal low-speed clock can't be turned off individually. It is controlled by CPUM0, CPUM1 (32K, watchdog disable) bits of OSCM register.

4.5 OSCM REGISTER

0CAH	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
OSCM	0	0	0	CPUM1	CPUM0	CLKMD	STPHX	0
Read/Write	-	-	-	R/W	R/W	R/W	R/W	-
After reset	-	-	-	0	0	0	0	-

The OSCM register is an oscillator control register. It controls oscillator status, system mode.

Bit 1 **STPHX:** Internal high-speed oscillator control bit.

0 = Internal high-speed oscillator free run.

- 1 = Internal high-speed oscillator free run stop. Internal low-speed RC oscillator is still running.
- Bit 2 **CLKMD:** System high/Low clock mode control bit. 0 = Normal (dual) mode. System clock is high clock. 1 = Slow mode. System clock is internal low clock.
- Bit[4:3] **CPUM[1:0]:** CPU operating mode control bits.
 - 00 = normal.
 - 01 = sleep (power down) mode.
 - 10 = green mode.
 - 11 = reserved.

"STPHX" bit controls internal high speed RC type oscillator operation. When "STPHX=0", the internal high speed RC type oscillator active. When "STPHX=1", the internal high speed RC type oscillator are disabled. T

4.6 SYSTEM CLOCK MEASUREMENT

Under design period, the users can measure system clock speed by software instruction cycle (Fcpu).

> Example: Fcpu instruction cycle of external oscillator.

	B0BSET	P0M.0	; Set P0.0 to be output mode for outputting Fcpu toggle signal.

4.7 SYSTEM CLOCK TIMING

Parameter	Symbol	Description	Typical
Hardware configuration time	Tcfg	2048*F _{ILRC}	64ms @ F _{ILRC} = 32KHz 128ms @ F _{ILRC} = 16KHz
Oscillator start up time	Tost	The start-up time is depended on oscillator's material, factory and architecture. The internal high speed RC type oscillator's start-up time is very short and ignored.	-
Oscillator warm-up time	Tosp	Oscillator warm-up time of reset condition. 2048*F _{hosc} (Power on reset, LVD reset, watchdog reset, external reset pin active.)	128us @ F _{hosc} = 16MHz
		Oscillator warm-up time of power down mode wake-up condition. 32*F _{hosc} Internal high-speed RC type oscillator.	2us @ F _{hosc} = 16MHz

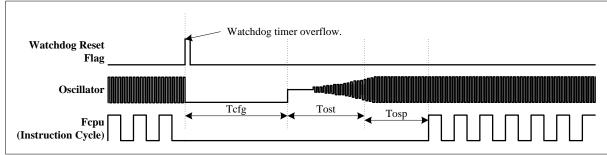

> Power On Reset Timing

External Reset Pin Reset Timing

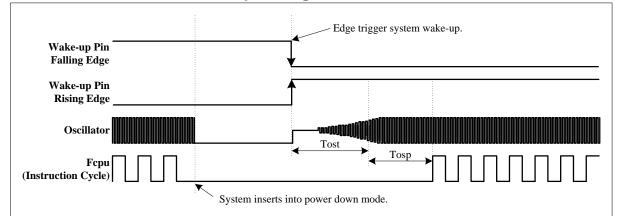

Watchdog Reset Timing

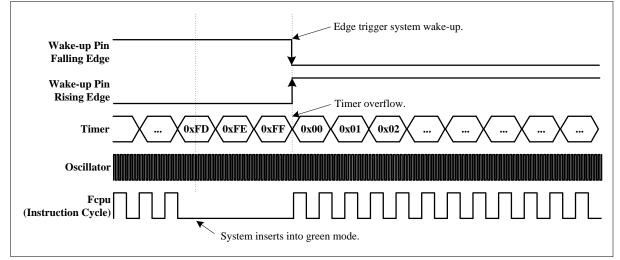

Power Down Mode Wake-up Timing

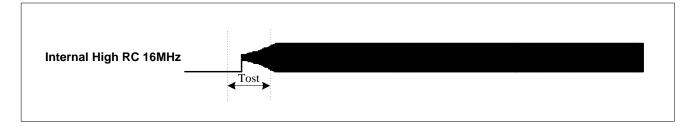

Green Mode Wake-up Timing

Oscillator Start-up Time

The start-up time is depended on oscillator's material, factory and architecture. The internal high speed RC type oscillator's start-up time is very short and ignored.

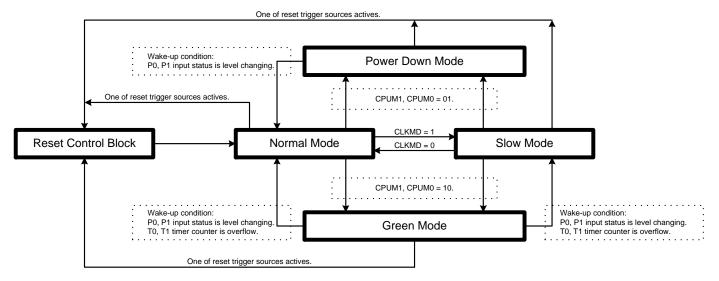

5 SYSTEM OPERATION MODE

5.1 OVERVIEW

The chip builds in four operating mode for difference clock rate and power saving reason. These modes control oscillators, op-code operation and analog peripheral devices' operation.

- Normal mode: System high-speed operating mode.
- Slow mode: System low-speed operating mode.
- Power down mode: System power saving mode (Sleep mode).
- Green mode: System ideal mode.

Operating Mode Control Block

Operating Mode Clock Control Table

Operating Mode	Normal Mode	Slow Mode	Green Mode	Power Down Mode
IHRC	Running	By STPHX	By STPHX	Stop
ILRC	Running	Running	Running	Stop
CPU instruction	Executing	Executing	Stop	Stop
T0 timer	By T0ENB	By T0ENB	By T0ENB	Inactive
TC0 timer	By TC0ENB	By TC0ENB	By TC0ENB (PWM active)	Inactive
TC1 timer	By TC1ENB	By TC1ENB	By TC1ENB (PWM active)	Inactive
T1 timer	By T1ENB	By T1ENB	By T1ENB	Inactive
Watchdog timer	By Watch_Dog	By Watch_Dog	By Watch_Dog	By Watch_Dog
	Code option	Code option	Code option	Code option
Internal interrupt	All active	All active	ТО	All inactive
External interrupt	All active	All active	All active	All inactive
Wakeup source	-	-	P0, P1, T0, CMP0, Reset	P0, P1, Reset

- **IHRC:** Internal high-speed oscillator RC type.
- ILRC: Internal low-speed oscillator RC type.

5.2 NORMAL MODE

The Normal Mode is system high clock operating mode. The system clock source is from high speed oscillator. The program is executed. After power on and any reset trigger released, the system inserts into normal mode to execute program. When the system is wake-up from power down mode, the system also inserts into normal mode. In normal mode, the high speed oscillator actives, and the power consumption is largest of all operating modes.

- The program is executed, and full functions are controllable.
- The system rate is high speed.
- The high speed oscillator and internal low speed RC type oscillator active.
- Normal mode can be switched to other operating modes through OSCM register.
- Power down mode is wake-up to normal mode.
- Slow mode is switched to normal mode.
- Green mode from normal mode is wake-up to normal mode.

5.3 SLOW MODE

The slow mode is system low clock operating mode. The system clock source is from internal low speed RC type oscillator. The slow mode is controlled by CLKMD bit of OSCM register. When CLKMD=0, the system is in normal mode. When CLKMD=1, the system inserts into slow mode. The high speed oscillator won't be disabled automatically after switching to slow mode, and must be disabled by SPTHX bit to reduce power consumption. In slow mode, the system rate is fixed Flosc/4 (Flosc is internal low speed RC type oscillator frequency).

- The program is executed, and full functions are controllable.
- The system rate is low speed (Flosc/4).
- The internal low speed RC type oscillator actives, and the high speed oscillator is controlled by STPHX=1. In slow mode, to stop high speed oscillator is strongly recommendation.
- Slow mode can be switched to other operating modes through OSCM register.
- Power down mode from slow mode is wake-up to normal mode.
- Normal mode is switched to slow mode.
- Green mode from slow mode is wake-up to slow mode.

5.4 POWER DOWN MODE

The power down mode is the system ideal status. No program execution and oscillator operation. Whole chip is under low power consumption status under 1uA. The power down mode is waked up by P0, P1 hardware level change trigger. P1 wake-up function is controlled by P1W register. Any operating modes into power down mode, the system is waked up to normal mode. Inserting power down mode is controlled by CPUM0 bit of OSCM register. When CPUM0=1, the system inserts into power down mode. After system wake-up from power down mode, the CPUM0 bit is disabled (zero status) automatically.

- The program stops executing, and full functions are disabled.
- All oscillators including external high speed oscillator, internal high speed oscillator and internal low speed oscillator stop.
- The power consumption is under 1uA.
- The system inserts into normal mode after wake-up from power down mode.
- The power down mode wake-up source is P0 and P1 level change trigger.

Note: If the system is in normal mode, to set STPHX=1 to disable the high clock oscillator. The system is under no system clock condition. This condition makes the system stay as power down mode, and can be wake-up by P0, P1 level change trigger.

5.5 GREEN MODE

The green mode is another system ideal status not like power down mode. In power down mode, all functions and hardware devices are disabled. But in green mode, the system clock source keeps running, so the power consumption of green mode is larger than power down mode. In green mode, the program isn't executed, but the timer with wake-up function actives as enabled, and the timer clock source is the non-stop system clock. The green mode has 2 wake-up sources. One is the P0, P1 level change trigger wake-up. The other one is internal timer with wake-up function occurring overflow. That's mean users can setup one fix period to timer, and the system is waked up until the time out. Inserting green mode is controlled by CPUM1 bit of OSCM register. When CPUM1=1, the system inserts into green mode. After system wake-up from green mode, the CPUM1 bit is disabled (zero status) automatically.

- The program stops executing, and full functions are disabled.
- Only the timer with wake-up function actives.
- The oscillator to be the system clock source keeps running, and the other oscillators operation is depend on system operation mode configuration.
- If inserting green mode from normal mode, the system insets to normal mode after wake-up.
- If inserting green mode from slow mode, the system insets to slow mode after wake-up.
- The green mode wake-up sources are P0, P1 level change trigger and unique time overflow.
- PWM and buzzer output functions active in green mode, but the timer can't wake-up the system as overflow.
- Note: Sonix provides "GreenMode" macro to control green mode operation. It is necessary to use "GreenMode" macro to control system inserting green mode. The macro includes three instructions. Please take care the macro length as using BRANCH type instructions, e.g. bts0, bts1, b0bts0, b0bts1, ins, incms, decs, decms, cmprs, jmp, or the routine would be error.

5.6 OPERATING MODE CONTROL MACRO

Sonix provides operating mode control macros to switch system operating mode easily.

Sonix provides operation	ing mode control	i macros to switch system operating mode easily.				
Macro	Length	Description				
SleepMode	1-word	The system insets into Sleep Mode (Power Down Mode).				
GreenMode	3-word	The system inserts into Green Mode.				
SlowMode	2-word	The system inserts into Slow Mode and stops high speed oscillator.				
Slow2Normal	5-word	The system returns to Normal Mode from Slow Mode. The macro				
		includes operating mode switch, enable high speed oscillator, high				
		speed oscillator warm-up delay time.				
Example: Switch normal/slow mode to power down (sleep) mode.						
Slee	pMode	; Declare "SleepMode" macro directly.				
> Example: Switc	h normal mode	to slow mode.				
Slow	Mode	; Declare "SlowMode" macro directly.				
•	h slow mode to ⁄2Normal	o normal mode (The external high-speed oscillator stops). ; Declare "Slow2Normal" macro directly.				
Example: Switc	h normal/slow i	mode to green mode.				
Gree	nMode	; Declare "GreenMode" macro directly.				
Example: Switc	h normal/slow ı	mode to green mode and enable T0 wake-up function.				
; Set T0 timer wakeup	function.					
BOBO	CLR FT	OIEN ; To disable T0 interrupt service				
BOBO		0ENB ; To disable T0 timer				
MOV	,	#20H ;				
B0M MOV		M,A ; To set T0 clock = Fcpu / 64 #74H				
BOM		; To set T0C initial value = 74H (To set T0 interval = 10 ms)				
BOBO		OIEN ; To disable T0 interrupt service				
B0B0		OIRQ ; To clear T0 interrupt request				
B0B	SET FT	OENB ; To enable T0 timer				

; Go into green mode GreenMode

; Declare "GreenMode" macro directly.

5.7 WAKEUP

5.7.1 OVERVIEW

Under power down mode (sleep mode) or green mode, program doesn't execute. The wakeup trigger can wake the system up to normal mode or slow mode. The wakeup trigger sources are external trigger (P0/P1 level change) and internal trigger (T0 timer overflow).

- Power down mode is waked up to normal mode. The wakeup trigger is only external trigger (P0/P1 level change)
- Green mode is waked up to last mode (normal mode or slow mode). The wakeup triggers are external trigger (P0/P1 level change) and internal trigger (T0 timer overflow).

5.7.2 WAKEUP TIME

When the system is in power down mode (sleep mode), the high clock oscillator stops. When waked up from power down mode, MCU waits for 32 internal high-speed oscillator clocks as the wakeup time to stable the oscillator circuit. After the wakeup time, the system goes into the normal mode.

Note: Wakeup from green mode is no wakeup time because the clock doesn't stop in green mode.

The value of the wakeup time is as the following.

The Wakeup time = 1/Fhosc * 32 (sec) + high clock start-up time

Example: In power down mode (sleep mode), the system is waked up. After the wakeup time, the system goes into normal mode. The wakeup time is as the following.

The wakeup time = 1/Fhosc * 32 = 2 us (Fhosc = 16MHz)

5.7.3 P1W WAKEUP CONTROL REGISTER

Under power down mode (sleep mode) and green mode, the I/O ports with wakeup function are able to wake the system up to normal mode. The wake-up trigger edge is level changing. When wake-up pin occurs rising edge or falling edge, the system is waked up by the trigger edge. The Port 0 and Port 1 have wakeup function. Port 0 wakeup function always enables, but the Port 1 is controlled by the P1W register.

0C0H	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
P1W	P17W	P16W	P15W	P14W	P13W	P12W	P11W	P10W
Read/Write	W	W	W	W	W	W	W	W
After reset	0	0	0	0	0	0	0	0

Bit[7:0] **P10W~P17W:** Port 1 wakeup function control bits.

0 = Disable P1n wakeup function.

1 = Enable P1n wakeup function.

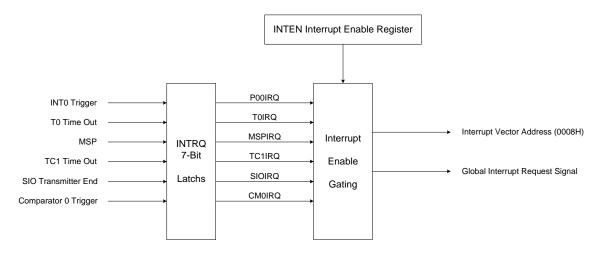

6 INTERRUPT

6.1 OVERVIEW

This MCU provides 6 interrupt sources, including 5 internal interrupt (T0/MSP/TC1/CM0/SIO) and 1 external interrupt (INT0). The external interrupt can wakeup the chip while the system is switched from power down mode to high-speed normal mode, and interrupt request is latched until return to normal mode. Once interrupt service is executed, the GIE bit in STKP register will clear to "0" for stopping other interrupt request. On the contrast, when interrupt service exits, the GIE bit will set to "1" to accept the next interrupts' request. The interrupt request signals are stored in INTRQ register.

Note: The GIE bit must enable during all interrupt operation.

6.2 INTEN INTERRUPT ENABLE REGISTER

INTEN is the interrupt request control register including three internal interrupts, two external interrupts enable control bits. One of the register to be set "1" is to enable the interrupt request function. Once of the interrupt occur, the stack is incremented and program jump to ORG 8 to execute interrupt service routines. The program exits the interrupt service routine when the returning interrupt service routine instruction (RETI) is executed.

0C9H	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
INTEN	CM0IEN	TC1IEN	-	TOIEN	SIOIEN	-	MSPIEN	P00IEN
Read/Write	R/W	R/W	-	R/W	R/W	-	R/W	R/W
After reset	0	0	-	0	0	-	0	0

- Bit 0 **POOIEN:** External P0.0 interrupt (INT0) control bit.
 - 0 = Disable INT0 interrupt function.
 - 1 = Enable INT0 interrupt function.
- Bit 1 **MSPIEN:** MSP interrupt control bit. 0 = Disable MSP interrupt function.
 - 1 = Enable MSP interrupt function.
- Bit 3 **SIOIEN:** SIO interrupt control bit. 0 = Disable SIO interrupt function. 1 = Enable SIO interrupt function.
- Bit 4 **TOIEN:** T0 timer interrupt control bit. 0 = Disable T0 interrupt function. 1 = Enable T0 interrupt function.
- Bit 6 **TC1IEN:** TC1 timer interrupt control bit. 0 = Disable TC1 interrupt function. 1 = Enable TC1 interrupt function.
- Bit 7 **CMOIEN:** Comparator 0 interrupt control bit. 0 = Disable comparator 0 interrupt function.
 - 1 = Enable comparator 0 interrupt function.

6.3 INTRQ INTERRUPT REQUEST REGISTER

INTRQ is the interrupt request flag register. The register includes all interrupt request indication flags. Each one of the interrupt requests occurs, the bit of the INTRQ register would be set "1". The INTRQ value needs to be clear by programming after detecting the flag. In the interrupt vector of program, users know the any interrupt requests occurring by the register and do the routine corresponding of the interrupt request.

0C8H	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
INTRQ	CM0IRQ	TC1IRQ	-	T0IRQ	SIOIRQ	-	MSPIRQ	P00IRQ
Read/Write	R/W	R/W	-	R/W	R/W	-	R/W	R/W
After reset	0	0	-	0	0	-	0	0

- Bit 0 **P00IRQ:** External P0.0 interrupt (INT0) request flag.
 - 0 =None INT0 interrupt request.
 - 1 = INT0 interrupt request.
- Bit 1 **MSPIRQ:** MSP interrupt request flag. 0 = None MSP interrupt request. 1 = MSP interrupt request.
- Bit 3 **SIOIRQ:** SIO interrupt request flag. 0 = None SIO interrupt request. 1 = SIO interrupt request.
- Bit 4 **TOIRQ:** T0 timer interrupt request flag. 0 = None T0 interrupt request. 1 = T0 interrupt request.
- Bit 6 **TC1IRQ:** TC1 timer interrupt request flag. 0 = None TC1 interrupt request. 1 = TC1 interrupt request.
- Bit 7 **CMOIRQ:** Comparator 0 interrupt request flag. 0 = None comparator 0 interrupt request. 1 = Comparator 0 interrupt request.

6.4 GIE GLOBAL INTERRUPT OPERATION

GIE is the global interrupt control bit. All interrupts start work after the GIE = 1 It is necessary for interrupt service request. One of the interrupt requests occurs, and the program counter (PC) points to the interrupt vector (ORG 8) and the stack add 1 level.

0DFH	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
STKP	GIE	-	-	-	-	STKPB2	STKPB1	STKPB0
Read/Write	R/W	-	-	-	-	R/W	R/W	R/W
After reset	0	-	-	-	-	1	1	1

Bit 7 **GIE:** Global interrupt control bit.

0 = Disable global interrupt.

1 = Enable global interrupt.

> Example: Set global interrupt control bit (GIE).

B0BSET FGIE

; Enable GIE

Note: The GIE bit must enable during all interrupt operation.

6.5 PUSH, POP ROUTINE

When any interrupt occurs, system will jump to ORG 8 and execute interrupt service routine. It is necessary to save ACC, PFLAG data. The chip includes "PUSH", "POP" for in/out interrupt service routine. The two instructions save and load **ACC**, **PFLAG** data into buffers and avoid main routine error after interrupt service routine finishing.

- * Note: "PUSH", "POP" instructions save and load ACC/PFLAG without (NT0, NPD). PUSH/POP buffer is an unique buffer and only one level.
- > Example: Store ACC and PAFLG data by PUSH, POP instructions when interrupt service routine executed.

	ORG JMP	0 START	
	ORG JMP	8 INT_SERVICE	
START:	ORG	10H	
INT_SERVICE:	PUSH		; Save ACC and PFLAG to buffers.
	POP		; Load ACC and PFLAG from buffers.
	RETI		; Exit interrupt service vector
	ENDP		

6.6 EXTERNAL INTERRUPT OPERATION (INT0)

INTO is external interrupt trigger source and builds in edge trigger configuration function. When the external edge trigger occurs, the external interrupt request flag will be set to "1" no matter the external interrupt control bit enabled or disable. When external interrupt control bit is enabled and external interrupt edge trigger is occurring, the program counter will jump to the interrupt vector (ORG 8) and execute interrupt service routine.

The external interrupt builds in wake-up latch function. That means when the system is triggered wake-up from power down mode, the wake-up source is external interrupt source (P0.0), and the trigger edge direction matches interrupt edge configuration, the trigger edge will be latched, and the system executes interrupt service routine fist after wake-up.

0BFH	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
PEDGE	-	-	-	P00G1	P00G0	-	-	-
Read/Write	-	-	-	R/W	R/W	-	-	-
After reset	-	-	-	1	0	-	-	-

Bit[4:3] **P00G[1:0]:** INT0 edge trigger select bits.

- 00 = reserved,
- 01 = rising edge,
- 10 = falling edge,
- 11 = rising/falling bi-direction.

> Example: Setup INT0 interrupt request and bi-direction edge trigger.

MOV B0MOV	A, #18H PEDGE, A	; Set INT0 interrupt trigger as bi-direction edge.
B0BSET	FP00IEN	; Enable INT0 interrupt service
B0BCLR	FP00IRQ	; Clear INT0 interrupt request flag
B0BSET	FGIE	; Enable GIE

> Example: INT0 interrupt service routine.

•	ORG JMP	8 INT_SERVICE	; Interrupt vector
INT_SERVICE:			; Push routine to save ACC and PFLAG to buffers.
	B0BTS1 JMP	FP00IRQ EXIT_INT	; Check P00IRQ ; P00IRQ = 0, exit interrupt vector
EXIT INT:	B0BCLR	FP00IRQ	; Reset P00IRQ ; INT0 interrupt service routine
			. Dep routing to load ACC and DELAC from buffers

RETI

- ; Pop routine to load ACC and PFLAG from buffers.
- ; Exit interrupt vector

6.7 TO INTERRUPT OPERATION

When the TOC counter occurs overflow, the TOIRQ will be set to "1" however the TOIEN is enable or disable. If the TOIEN = 1, the trigger event will make the TOIRQ to be "1" and the system enter interrupt vector. If the TOIEN = 0, the trigger event will make the TOIRQ to be "1" but the system will not enter interrupt vector. Users need to care for the operation under multi-interrupt situation.

> Example: T0 interrupt request setup.

B0BCLR	FT0IEN	; Disable T0 interrupt service
B0BCLR	FT0ENB	; Disable T0 timer
MOV	A, #20H	;
B0MOV	T0M, A	; Set T0 clock = Fcpu / 64
MOV	A, #74H	; Set T0C initial value = 74H
B0MOV	T0C, A	; Set T0 interval = 10 ms
B0BSET	FT0IEN	; Enable T0 interrupt service
B0BCLR	FT0IRQ	; Clear T0 interrupt request flag
B0BSET	FT0ENB	; Enable T0 timer
B0BSET	FGIE	; Enable GIE

> Example: T0 interrupt service routine.

INT_SERVICE:	ORG JMP	8 INT_SERVICE	; Interrupt vector
			; Push routine to save ACC and PFLAG to buffers.
	B0BTS1 JMP	FT0IRQ EXIT_INT	; Check T0IRQ ; T0IRQ = 0, exit interrupt vector
	B0BCLR MOV B0MOV 	FT0IRQ A, #74H T0C, A	; Reset T0IRQ ; Reset T0C. ; T0 interrupt service routine
EXIT_INT:			; Pop routine to load ACC and PFLAG from buffers.
	RETI		; Exit interrupt vector

6.8 TC1 INTERRUPT OPERATION

When the TC1C counter overflows, the TC1IRQ will be set to "1" no matter the TC1IEN is enable or disable. If the TC1IEN and the trigger event TC1IRQ is set to be "1". As the result, the system will execute the interrupt vector. If the TC1IEN = 0, the trigger event TC1IRQ is still set to be "1". Moreover, the system won't execute interrupt vector even when the TC1IEN is set to be "1". Users need to be cautious with the operation under multi-interrupt situation.

> Example: TC1 interrupt request setup. Fcpu = 16Mhz / 16.

BOBCLR	FTC1IEN	; Disable TC1 interrupt service
BOBCLR	FTC1ENB	; Disable TC1 timer
MOV	A, #20H	;
BOMOV	TC1M, A	; Set TC1 clock = Fcpu / 64
MOV	A, #64H	; Set TC1C initial value = 64H
BOMOV	TC1C, A	; Set TC1 interval = 10 ms
B0BSET	FTC1IEN	; Enable TC1 interrupt service
B0BCLR	FTC1IRQ	; Clear TC1 interrupt request flag
B0BSET	FTC1ENB	; Enable TC1 timer
BOBSET	FGIE	; Enable GIE

> Example: TC1 interrupt service routine.

INT_SERVICE:	ORG JMP	8 INT_SERVICE	; Interrupt vector
			; Push routine to save ACC and PFLAG to buffers.
	B0BTS1 JMP	FTC1IRQ EXIT_INT	; Check TC1IRQ ; TC1IRQ = 0, exit interrupt vector
	B0BCLR MOV B0MOV 	FTC1IRQ A, #74H TC1C, A	; Reset TC1IRQ ; Reset TC1C. ; TC1 interrupt service routine
EXIT_INT:	 RETI		; Pop routine to load ACC and PFLAG from buffers. ; Exit interrupt vector

6.9 SIO INTERRUPT OPERATION

When the SIO converting successfully, the SIOIRQ will be set to "1" no matter the SIOIEN is enable or disable. If the SIOIEN and the trigger event SIOIRQ is set to be "1". As the result, the system will execute the interrupt vector. If the SIOIEN = 0, the trigger event SIOIRQ is still set to be "1". Moreover, the system won't execute interrupt vector even when the SIOIEN is set to be "1". Users need to be cautious with the operation under multi-interrupt situation.

> Example: SIO interrupt request setup.

B0BSET	FSIOIEN	; Enable SIO interrupt service
B0BCLR	FSIOIRQ	; Clear SIO interrupt request flag
B0BSET	FGIE	; Enable GIE

> Example: SIO interrupt service routine.

INT SERVICE:	ORG JMP	8 INT_SERVICE	Check SIOIRQ SIOIRQ = 0, exit interrupt vector Reset SIOIRQ
			; Push routine to save ACC and PFLAG to buffers.
	B0BTS1 JMP	FSIOIRQ EXIT_INT	; Check SIOIRQ ; SIOIRQ = 0, exit interrupt vector
	B0BCLR 	FSIOIRQ	; Reset SIOIRQ ; SIO interrupt service routine
EXIT_INT:			; Pop routine to load ACC and PFLAG from buffers.
	RETI		; Exit interrupt vector

6.10 COMPARATOR INTERRUPT OPERATION (CMP0)

Sonix provides one comparator with interrupt function in the micro-controller. The comparator interrupt trigger edge direction depends on CM0G. When the comparator output status transition occurs, the comparator interrupt request flag will be set to "1" no matter the comparator interrupt control bit status. The comparator interrupt flag doesn't active only when comparator control bit is disabled. When comparator interrupt control bit is enabled and comparator interrupt edge trigger is occurring, the program counter will jump to the interrupt vector (ORG 8) and execute interrupt service routine.

> Example: Setup comparator 0 interrupt request.

B0BSET	FCM0IEN	; Enable comparator 0 interrupt service
B0BCLR	FCM0IRQ	; Clear comparator 0 interrupt request flag
B0BSET	FCM0EN	; Enable comparator 0.
B0BSET	FGIE	; Enable GIE

> Example: Comparator 0 interrupt service routine.

INT_SERVICE:	ORG JMP	8 INT_SERVICE	; Interrupt vector		
			; Push routine to save ACC and PFLAG to buffers.		
	B0BTS1 JMP	FCM0IRQ EXIT_INT	; Check CM0IRQ ; CM0IRQ = 0, exit interrupt vector		
EXIT_INT:	B0BCLR	FCM0IRQ	; Reset CM0IRQ ; Comparator 0 interrupt service routine		
	 RETI		; Pop routine to load ACC and PFLAG from buffers. ; Exit interrupt vector		

7 I/O PORT

7.1 OVERVIEW

The micro-controller builds in 22 pin I/O. Most of the I/O pins are mixed with analog pins and special function pins. The I/O shared pin list is as following.

I/O F	Pin	Shared F	Pin	Shared Pin Control Condition	
Name	Туре	Name	Туре		
P0.0	I/O	INT0	DC	P00IEN=1

After reset	-	-	-	0	0	0	-	-

- Bit 2 **P50OC:** P5.0 open-drain control bit
 - 0 = Disable open-drain mode
 - 1 = Enable open-drain mode
- Bit 3 **P51OC:** P5.1 open-drain control bit
 - 0 = Disable open-drain mode
 - 1 = Enable open-drain mode
- Bit 4 **P52OC:** P5.2 open-drain control bit
 - 0 = Disable open-drain mode
 - 1 = Enable open-drain mode

Example: Enable P5.0 to open-drain mode and output high.

BOBSET	P5.0	; Set P5.0 buffer high.
B0BSET MOV B0MOV	P50M A, #04H P1OC, A	; Enable P5.0 output mode. ; Enable P5.0 open-drain function.

Note: P1OC is write only register. Setting P10OC must be used "MOV" instructions.

> Example: Disable open-drain mode.

- MOVA, #0; Disable open-drain function.B0MOVP1OC, A
- * Note: After disable open-drain function, I/O mode returns to last I/O mode.

8 TIMERS

8.1 WATCHDOGTIMER

The watchdog timer (WDT) is a binary up counter designed for monitoring program execution. If the program goes into the unknown status by noise interference, WDT overflow signal raises and resets MCU. Watchdog clock controlled by code option and the clock source is internal low-speed oscillator.

Watchdog overflow time = 8192 / Internal Low-Speed oscillator (sec).

VDD	Internal Low RC Freq.	Watchdog Overflow Time
3V	16KHz	512ms
5V	32KHz	256ms

The watchdog timer has three operating options controlled "WatchDog" code option.

- **Disable:** Disable watchdog timer function.
- **Enable:** Enable watchdog timer function. Watchdog timer actives in normal mode and slow mode. In power down mode and green mode, the watchdog timer stops.
- Always_On: Enable watchdog timer function. The watchdog timer actives and not stop in power down mode and green mode.

In high noisy environment, the "Always_On" option of watchdog operations is the strongly recommendation to make the system reset under error situations and re-start again.

Watchdog clear is controlled by WDTR register. Moving **0x5A** data into WDTR is to reset watchdog timer.

0CCH	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
WDTR	WDTR7	WDTR6	WDTR5	WDTR4	WDTR3	WDTR2	WDTR1	WDTR0
Read/Write	W	W	W	W	W	W	W	W
After reset	0	0	0	0	0	0	0	0

Example: An operation of watchdog timer is as following. To clear the watchdog timer counter in the top of the main routine of the program.

Main:

MOV B0MOV	A, #5AH WDTR, A	; Clear the watchdog timer.
CALL CALL	SUB1 SUB2	
 JMP	MAIN	

> Example: Clear watchdog timer by "@RST_WDT" macro of Sonix IDE.

Main:

@RST_WDT		
CALL CALL	SUB1 SUB2	
 JMP	MAIN	

SONiX TECHNOLOGY CO., LTD

; Clear the watchdog timer.

Watchdog timer application note is as following.

- Before clearing watchdog timer, check I/O status and check RAM contents can improve system error.
- Don't clear watchdog timer in interrupt vector and interrupt service routine. That can improve main routine fail.
- Clearing watchdog timer program is only at one part of the program. This way is the best structure to enhance the watchdog timer function.
- Example: An operation of watchdog timer is as following. To clear the watchdog timer counter in the top of the main routine of the program.

Main: ; Check I/O. ... : Check RAM JMP \$; I/O or RAM error. Program jump here and don't Err: ; clear watchdog. Wait watchdog timer overflow to reset IC. Correct: ; I/O and RAM are correct. Clear watchdog timer and ; execute program. MOV A, #5AH ; Clear the watchdog timer. **B0MOV** WDTR, A . . . CALL SUB1 SUB2 CALL JMP MAIN

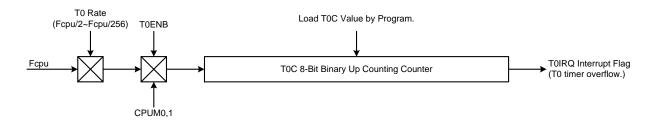

8.2 T0 8-BIT BASIC TIMER

8.2.1 OVERVIEW

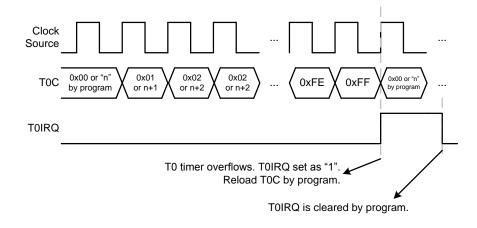

The T0 timer is an 8-bit binary up timer with basic timer function. The basic timer function supports flag indicator (T0IRQ bit) and interrupt operation (interrupt vector). The interval time is programmable through T0M, T0C registers. The T0 builds in green mode wake-up function. When T0 timer overflow occurs under green mode, the system will be waked-up to last operating mode.

- 8-bit programmable up counting timer: Generate time-out at specific time intervals based on the selected clock frequency.
- Interrupt function: T0 timer function supports interrupt function. When T0 timer occurs overflow, the T0IRQ actives and the system points program counter to interrupt vector to do interrupt sequence.
- Green mode function: T0 timer keeps running in green mode and wakes up system when T0 timer overflows.

8.2.2 T0 TIMER OPERATION

T0 timer is controlled by T0ENB bit. When T0ENB=0, T0 timer stops. When T0ENB=1, T0 timer starts to count. T0C increases "1" by timer clock source. When T0 overflow event occurs, T0IRQ flag is set as "1" to indicate overflow and cleared by program. The overflow condition is T0C count from full scale (0xFF) to zero scale (0x00). T0 doesn't build in double buffer, so load T0C by program when T0 timer overflows to fix the correct interval time. If T0 timer interrupt function is enabled (T0IEN=1), the system will execute interrupt procedure. The interrupt procedure is system program counter points to interrupt vector (ORG 8) and executes interrupt service routine after T0 overflow occurrence. Clear T0IRQ by program is necessary in interrupt procedure. T0 timer can works in normal mode, slow mode and green mode. In green mode, T0 keeps counting, set T0IRQ and wakes up system when T0 timer overflows.

T0 clock source is Fcpu (instruction cycle) through T0rate[2:0] pre-scaler to decide Fcpu/2~Fcpu/256. T0 length is 8-bit (256 steps), and the one count period is each cycle of input clock.

		T0 Interval Time						
T0rate[2:0]	T0 Clock	Fhosc=1 Fcpu=Fl		Fhosc=16MHz, Fcpu=Fhosc/16				
		max. (ms)	Unit (us)	max. (ms)	Unit (us)			
000b	Fcpu/256	16.384	64	65.536	256			
001b	Fcpu/128	8.192	32	32.768	128			
010b	Fcpu/64	4.096	16	16.384	64			
011b	Fcpu/32	2.048	8	8.192	32			
100b	Fcpu/16	1.024	4	4.096	16			
101b	Fcpu/8	0.512	2	2.048	8			
110b	Fcpu/4	0.256	1	1.024	4			
111b	Fcpu/2	0.128	0.5	0.512	2			

8.2.3 TOM MODE REGISTER

T0M is T0 timer mode control register to configure T0 operating mode including T0 pre-scaler, clock source...These configurations must be setup completely before enabling T0 timer.

0D8H	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
ТОМ	T0ENB	T0rate2	T0rate1	T0rate0	-	-	-	-
Read/Write	R/W	R/W	R/W	R/W	-	-	-	-
After reset	0	0	0	0	-	-	-	-

Bit [6:4] **TORATE[2:0]:** TO timer clock source select bits.

000 = Fcpu/256, 001 = Fcpu/128, 010 = Fcpu/64, 011 = Fcpu/32, 100 = Fcpu/16, 101 = Fcpu/8, 110 = Fcpu/4,111 = Fcpu/2.

- Bit 7 **T0ENB:** T0 counter control bit.
 - 0 = Disable T0 timer.
 - 1 = Enable T0 timer.

8.2.4 TOC COUNTING REGISTER

TOC is T0 8-bit counter. When T0C overflow occurs, the T0IRQ flag is set as "1" and cleared by program. The T0C decides T0 interval time through below equation to calculate a correct value. It is necessary to write the correct value to T0C register, and then enable T0 timer to make sure the fist cycle correct. After one T0 overflow occurs, the T0C register is loaded a correct value by program.

0D9H	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
T0C	T0C7	T0C6	T0C5	T0C4	T0C3	T0C2	T0C1	T0C0
Read/Write	R/W							
After reset	0	0	0	0	0	0	0	0

The equation of TOC initial value is as following.

T0C initial value = 256 - (T0 interrupt interval time * T0 clock rate)

Example: To calculation T0C to obtain 10ms T0 interval time. T0 clock source is Fcpu = 16MHz/16 = 1MHz. Select T0RATE=001 (Fcpu/128).

T0 interval time = 10ms. T0 clock rate = 16MHz/16/128

TOC initial value = 256 - (T0 interval time * input clock)= 256 - (10ms * 16MHz / 16 / 128)= 256 - (10⁻² * 16MHz / 16 / 128)= B2H

8.2.5 T0 TIMER OPERATION EXPLAME

T0 TIMER CONFIGURATION:

; Enable T0 interrupt function.

; Enable T0 timer.

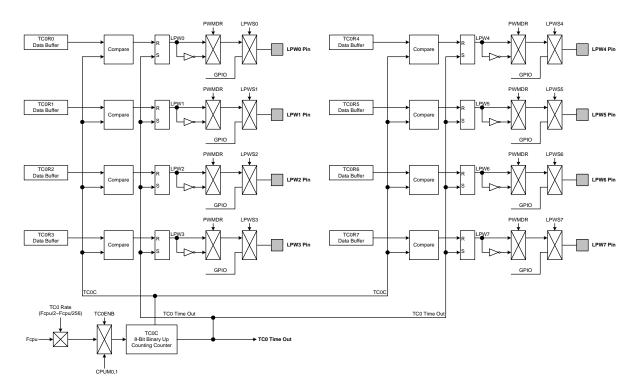

8.3 8-CH LED PWM Driver (TC0)

8.3.1 OVERVIEW

The TC0 timer is an 8-bit binary up timer, and the main purpose is to generator 8-ch PWM outputs. TC0 doesn't support normal timer function and interrupt function. TC0C 256-step period decides PWM's cycle through TC0rate[2:0] setting TC0 clock rate. TC0R0~TC0R7 decide each channel of 8 PWMs' duty. When TC0C=0, PWM output pulse status. When TC0C=TC0R, PWM exchanges to idle status to generator PWM's duty. The PWM phase is controlled by PWMDR bit. When PWMDR=0, PWM status is idle low and high duty. When PWMDR=1, PWM status is idle high and low duty. The main purpose of the TC0 timer is as following. TC0Rn is not auto-reload designed. If modify PWM duty as PWM outputting through TC0Rn registers, the PWM output waveform will change immediately.

- **PWM output:** The PWM is duty/cycle programmable controlled by TC0rate, TC0Rn and LPWS register.
- Green mode function: TC0's PWM function keeps running in green mode.

8.3.2 TCOM CONTROL REGISTER

0DAH	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0

8.3.3 TC0 PWM OPERATION

TC0 PWM cycle is TC0C 0x00~0xFF period controlled by TC0Rate[2:0] bits. It is not to set TC0C initial value, and only to clear TC0C before setting TC0ENB. TC0 PWM has 8 channels selected by LPWS register. If the bit of LPWS register is set, the channel is switched to LED PWM output mode and isolates GPIO function. If the bit is cleared, the channel returns to GPIO mode and GPIO last status. It is easy to set PWM idle status as PWM non-output mode.

8.4 TC1 8-BIT TIMER

8.4.1 OVERVIEW

The TC1 timer is an 8-bit binary up timer with basic timer and PWM functions. The basic timer function supports flag indicator (TC1IRQ bit) and interrupt operation (interrupt vector). The interval time is programmable through TC1M, TC1C, TC1R registers. TC1 builds in duty/cycle programmable PWM. The PWM cycle and resolution are controlled by TC1 timer clock rate, TC1R and TC1D registers, so the PWM with good flexibility to implement IR carry signal, motor control and brightness adjuster...The main purposes of the TC1 timer are as following.

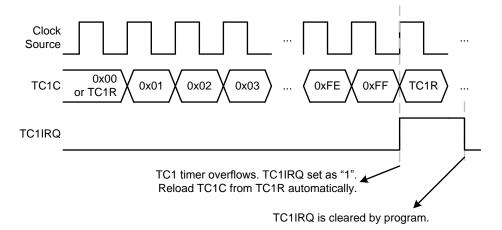

- 8-bit programmable up counting timer: Generate time-out at specific time intervals based on the selected clock frequency.
- Interrupt function: TC1 timer function supports interrupt function. When TC1 timer occurs overflow, the TC1IRQ actives and the system points program counter to interrupt vector to do interrupt sequence.
- Duty/cycle programmable PWM: The PWM is duty/cycle programmable controlled by TC1R and TC1D registers.
- Green mode function: All TC1 functions (timer, PWM, auto-reload) keep running in green mode and no wake-up function.

8.4.2 TC1 TIMER OPERATION

TC1 timer is controlled by TC1ENB bit. When TC1ENB=0, TC1 timer stops. When TC1ENB=1, TC1 timer starts to count. Before enabling TC1 timer, setup TC1 timer's configurations to select timer function modes, e.g. basic timer, interrupt function...TC1C increases "1" by timer clock source. When TC1 overflow event occurs, TC1IRQ flag is set as "1" to indicate overflow and cleared by program. The overflow condition is TC1C count from full scale (0xFF) to zero scale (0x00). In difference function modes, TC1C value relates to operation. If TC1C value changing effects operation, the transition of operations would make timer function error. So TC1 builds in double buffer to avoid these situations happen. The double buffer concept is to flash TC1C during TC1 counting, to set the new value to TC1R (reload buffer), and the new value will be loaded from TC1R to TC1C after TC1 overflow occurrence automatically. In the next cycle, the TC1 timer runs under new conditions, and no any transitions occur. The auto-reload function is no any control interface and always actives as TC1 enables. If TC1 timer interrupt function is enabled (TC1IEN=1), the system will execute interrupt procedure. The interrupt procedure is system program counter points to interrupt vector (ORG 8) and executes interrupt service routine after TC1 overflow occurrence. Clear TC1IRQ by program is necessary in interrupt procedure. TC1 timer can works in normal mode, slow mode and green mode. But in green mode, TC1 keep counting, set TC1IRQ and outputs PWM, but can't wake-up system.

TC1 provides different clock sources to implement different applications and configurations. TC1 clock source includes Fcpu (instruction cycle) and Fhosc (high speed oscillator) controlled by TC1CKS0 bits. TC1CKS0 bit selects the clock source is from Fcpu or Fhosc. If TC1CKS0=0, TC1 clock source is Fcpu through TC1rate[2:0] pre-scaler to decide Fcpu/1~Fcpu/128. If TC1CKS0=1, TC1 clock source is Fhosc without any divider. TC1rate[2:0] pre-scaler is unless when TC1CKS0=1 condition. TC1 length is 8-bit (256 steps), and the one count period is each cycle of input clock.

TC1CKS0	TC1rate[2:0]	TC1 Clock	TC1 Interval Time Fhosc=16MHz, Fcpu=Fhosc/2		
			max. (ms)	Unit (us)	
0	000b	Fcpu/128	4.096	16	
0	001b	Fcpu/64	2.048	8	
0	010b	Fcpu/32	1.024	4	
0	011b	Fcpu/16	0.512	2	
0	100b	Fcpu/8	0.256	1	
0	101b	Fcpu/4	0.128	0.5	
0	110b	Fcpu/2	0.064	0.25	
0	111b	Fcpu/1	0.032	0.125	
1	useless	Fhosc	0.016	0.0625	

8.4.3 TC1M MODE REGISTER

TC1M is TC1 timer mode control register to configure TC1 operating mode including TC1 pre-scaler, clock source, PWM function...These configurations must be setup completely before enabling TC1 timer.

0DCH	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
TC1M	TC1ENB	TC1rate2	TC1rate1	TC1rate0	-	TC1CKS0	-	PWM10UT
Read/Write	R/W	R/W	R/W	R/W	-	R/W	-	R/W
After reset	0	0	0	0	-	0	-	0

Bit 0 **PWM1OUT:** PWM output control bit.

0 = Disable PWM output function, and P5.3 is GPIO mode.

1 = Enable PWM output function, and P5.3 outputs PWM signal.

- TC1CKS0: TC1 clock source select bit.
 - 0 = Fcpu.

Bit 2

1 = Fhosc. TC1rate[2:0] bits are useless.

- Bit 7 **TC1ENB:** TC1 counter control bit.
 - 0 = Disable TC1 timer.
 - 1 = Enable TC1 timer.

8.4.4 TC1C COUNTING REGISTER

TC1C is TC1 8-bit counter. When TC1C overflow occurs, the TC1IRQ flag is set as "1" and cleared by program. The TC1C decides TC1 interval time through below equation to calculate a correct value. It is necessary to write the correct value to TC1C register and TC1R register first time, and then enable TC1 timer to make sure the fist cycle correct. After one TC1 overflow occurs, the TC1C register is loaded a correct value from TC1R register automatically, not program.

0DDH	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
TC1C	TC1C7	TC1C6	TC1C5	TC1C4	TC1C3	TC1C2	TC1C1	TC1C0
Read/Write	R/W							
After reset	0	0	0	0	0	0	0	0

The equation of TC1C initial value is as following.

TC1C initial value = 256 - (TC1 interrupt interval time * TC1 clock rate)

Bit [6:4] **TC1RATE[2:0]:** TC1 timer clock source select bits. 000 = Fcpu/128, 001 = Fcpu/64, 010 = Fcpu/32, 011 = Fcpu/16, 100 = Fcpu/8, 101 = Fcpu/4, 110 = Fcpu/2, 111 = Fcpu/1.

8.4.5 TC1R AUTO-RELOAD REGISTER

TC1 timer builds in auto-reload function, and TC1R register stores reload data. When TC1C overflow occurs, TC1C register is loaded data from TC1R register automatically. Under TC1 timer counting status, to modify TC1 interval time is to modify TC1R register, not TC1C register. New TC1C data of TC1 interval time will be updated after TC1 timer overflow occurrence, TC1R loads new value to TC1C register. But at the first time to setup T0M, TC1C and TC1R must be set the same value before enabling TC1 timer. TC1 is double buffer design. If new TC1R value is set by program, the new value is stored in 1st buffer. Until TC1 overflow occurs, the new value moves to real TC1R buffer. This way can avoid any transitional condition to effect the correctness of TC1 interval time and PWM output signal.

0DEH	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
TC1R	TC1R7	TC1R6	TC1R5	TC1R4	TC1R3	TC1R2	TC1R1	TC1R0
Read/Write	W	W	W	W	W	W	W	W
After reset	0	0	0	0	0	0	0	0

The equation of TC1R initial value is as following.

TC1R initial value = 256 - (TC1 interrupt interval time * TC1 clock rate)

Example: To calculation TC1C and TC1R value to obtain 10ms TC1 interval time. TC1 clock source is Fcpu = 16MHz/16 = 1MHz. Select TC1RATE=000 (Fcpu/128). TC1 interval time = 10ms. TC1 clock rate = 16MHz/16/128

TC1C/TC1R initial value = 256 - (TC1 interval time * input clock)

= 256 - (10ms * 16MHz / 16 / 128)

= 256 - (10-2 * 16 * 106 / 16 / 128)

= B2H

8.4.6 TC1D PWM DUTY REGISTER

TC1D register's purpose is to decide PWM duty. In PWM mode, TC1R controls PWM's cycle, and TC1D controls the duty of PWM. The operation is base on timer counter value. When TC1C = TC1D, the PWM high duty finished and exchange to low level. It is easy to configure TC1D to choose the right PWM's duty for application.

0EAH	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
TC1D	TC1D7	TC1D6	TC1D5	TC1D4	TC1D3	TC1D2	TC1D1	TC1D0
Read/Write	R/W							
After Reset	0	0	0	0	0	0	0	0

The equation of TC1D initial value is as following.

TC1D initial value = TC1R + (PWM high pulse width period / TC1 clock rate)

Example: To calculate TC1D value to obtain 1/3 duty PWM signal. The TC1 clock source is Fcpu = 16MHz/16 = 1MHz. Select TC1RATE=000 (Fcpu/128).

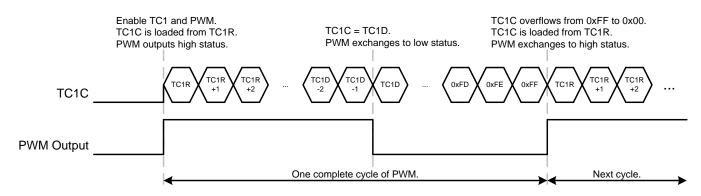

TC1R = B2H. TC1 interval time = 10ms. So the PWM cycle is 100Hz. In 1/3 duty condition, the high pulse width is about 3.33ms.

TC1D initial value = B2H + (PWM high pulse width period / TC1 clock rate)= B2H + (3.33ms * 16MHz / 16 / 128)= B2H + 1AH= CCH

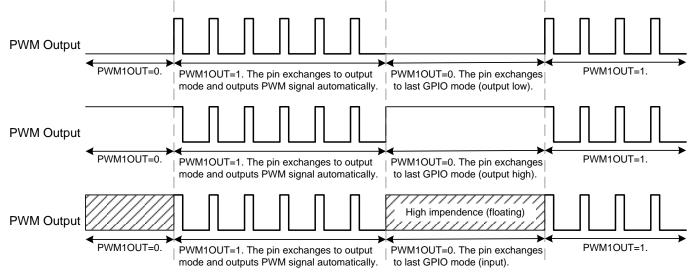

8.4.7 PULSE WIDTH MODULATION (PWM)

The PWM is duty/cycle programmable design to offer various PWM signals. When TC1 timer enables and PWM1OUT bit sets as "1" (enable PWM output), the PWM output pin (P5.3) outputs PWM signal. One cycle of PWM signal is high pulse first, and then low pulse outputs. TC1R register controls the cycle of PWM, and TC1D decides the duty (high pulse width length) of PWM. TC1C initial value is TC1R reloaded when TC1 timer enables and TC1 timer overflows. When TC1C count is equal to TC1D, the PWM high pulse finishes and exchanges to low level. When TC1 overflows (TC1C counts from 0xFF to 0x00), one complete PWM cycle finishes. The PWM exchanges to high level for next cycle. The PWM is auto-reload design to load TC1C from TC1R automatically when TC1 overflows and the end of PWM's cycle, to keeps PWM continuity. If modify the PWM cycle by program as PWM outputting, the new cycle occurs at next cycle when TC1C loaded from TC1R.

The resolution of PWM is decided by TC1R. TC1R range is from 0x00~0xFF. If TC1R = 0x00, PWM's resolution is 1/256. If TC1R = 0x80, PWM's resolution is 1/128. TC1D controls the high pulse width of PWM for PWM's duty. When TC1C = TC1D, PWM output exchanges to low status. TC1D must be greater than TC1R, or the PWM signal keeps low status. When PWM outputs, TC1IRQ still actives as TC1 overflows, and TC1 interrupt function actives as TC1IEN = 1. But strongly recommend be careful to use PWM and TC1 timer together, and make sure both functions work well. The PWM output pin is shared with GPIO and switch to output PWM signal as PWM1OUT=1 automatically. If PWM1OUT bit is cleared to disable PWM, the output pin exchanges to last GPIO mode automatically. It easily to implement carry signal on/off operation, not to control TC1ENB bit.

8.4.8 TC1 TIMER OPERATION EXPLAME

9 SERIAL INPUT/OUTPUT TRANSCEIVER (SIO)

9.1 OVERVIEW

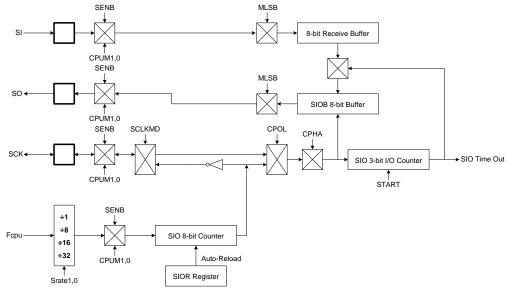

The SIO (serial input/output) transceiver is a serial communicate interface for data exchanging from one MCU to one MCU or other hardware peripherals. It is a simple 8-bit interface without a major definition of protocol, packet or control bits. The SIO transceiver includes three pins, clock (SCK), data input (SI) and data output (SO) to send data between master and slaver terminals. The SIO interface builds in 8-mode which are the clock idle status, the clock phases and data fist bit direction. The 8-bit mode supports most of SIO/SPI communicate format.

The SIO features include the following:

- Full-duplex, 3-wire synchronous data transfer.
- Master (SCK is clock output) or Slave (SCK is clock input) operation.
- MSB/LSB first data transfer.
- The start phase of data sampling location selection is 1st-phase or 2nd-phase controlled register.
- SCK, SI, SO are programmable open-drain output pin for multiple salve devices application.
- Two programmable bit rates (Only in master mode).
- End-of-Transfer interrupt.

9.2 SIO OPERATION

The SIOM register can control SIO operating function, such as: transmit/receive, clock rate, data transfer direction, SIO clock idle status and clock control phase and starting this circuit. This SIO circuit will transmit or receive 8-bit data automatically by setting SENB and START bits in SIOM register. The SIO data buffer is double buffer design. When the SIO operating, the SIOB register stores transfer data and one internal buffer stores receive data. When SIO operation is successfully, the internal buffer reloads into SIOB register automatically. The SIO 8-bit counter and SIOR register are designed to generate SIO's clock source with auto-reload function. The 3-bit I/O counter can monitor the operation of SIO and announce an interrupt request after transmitting/ receiving 8-bit data. After transferring 8-bit data, this circuit will be disabled automatically and re-transfer data by programming SIOM register. CPOL bit is designed to control SIO clock idle status. CPHA bit is designed to control the clock edge direction of data receive. CPOL and CPHA bits decide the SIO format. The SIO data transfer direction is controlled by MLSB bit to decide MSB first or LSB first.

SIO Interface Circuit Diagram

The SIO supports 8-mode format controlled by MLSB, CPOL and CPHA bits. The edge direction is "Data Transfer Edge". When setting rising edge, that means to receive and transmit one bit data at SCK rising edge, and data transition is at SCK falling edge. When setting falling edge, that means to receive and transmit one bit data at SCK falling edge, and data transition is at SCK rising edge.

"CPHA" is the clock phase bit controls the phase of the clock on which data is sampled. When CPHA=1, the SCK first edge is for data transition, and receive and transmit data is at SCK 2nd edge. When CPHA=0, the 1st bit is fixed already, and the SCK first edge is to receive and transmit data. The SIO data transfer timing as following figure:

M L S B	C P O L	C P H A	Diagrams	Description
0	0	1	bit7 / bit6 / bit5 / bit4 / bit3 / bit2 / bit1 / bit0	SCK idle status = Low. The transfer first bit = MSB. SCK data transfer edge = Falling edge.
0	1	1	bit7 / bit6 / bit5 / bit4 / bit3 / bit2 / bit1 / bit0	SCK idle status = High. The transfer first bit = MSB. SCK data transfer edge = Rising edge.
0	0	0	bit7 X bit6 X bit5 X bit4 X bit3 X bit2 X bit1 X bit0 X Next data	SCK idle status = Low. The transfer first bit = MSB. SCK data transfer edge = Rising edge.
0	1	0	bit7 X bit6 X bit5 X bit4 X bit3 X bit2 X bit1 X bit0 X Next data	SCK idle status = High. The transfer first bit = MSB. SCK data transfer edge = Falling edge.
1	0	1	bit0 / bit1 / bit2 / bit3 / bit4 / bit5 / bit6 / Bit7	SCK idle status = Low. The transfer first bit = LSB. SCK data transfer edge = Falling edge.
1	1	1	bit0 / bit1 / bit2 / bit3 / bit4 / bit5 / bit6 / Bit7	SCK idle status = High. The transfer first bit = LSB. SCK data transfer edge = Rising edge.
1	0	0	bit0 \log bit1 \log bit2 \log bit3 \log bit4 \log bit5 \log bit6 \log Bit7 \log Next data	SCK idle status = Low. The transfer first bit = LSB. SCK data transfer edge = Rising edge.
1	1	0	bit0 X bit1 X bit2 X bit3 X bit4 X bit5 X bit6 X Bit7 X Next data	SCK idle status = High. The transfer first bit = LSB. SCK data transfer edge = Falling edge.

SIO Data Transfer Timing

The SIO supports interrupt function. SIOIEN is SIO interrupt function control bit. SIOIEN=0, disable SIO interrupt function. SIOIEN=1, enable SIO interrupt function. When SIO interrupt function enable, the program counter points to interrupt vector (ORG 8) to do SIO interrupt service routine after SIO operating. SIOIRQ is SIO interrupt request flag, and also to be the SIO operating status indicator when SIOIEN = 0, but cleared by program. When SIO operation finished, the SIOIRQ would be set to "1", and the operation is the inverse status of SIO "START" control bit.

The SIOIRQ and SIO START bit indicating the end status of SIO operation is after one 8-bit data transferring. The duration from SIO transfer end to SIOIRQ/START active is about "1/2*SIO clock", means the SIO end indicator doesn't active immediately.

Note: The first step of SIO operation is to setup the SIO pins' mode. Enable SENB, select CPOL and CPHA bits. These bits control SIO pins' mode.

9.3 SIOM MODE REGISTER

0B4H	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
SIOM	SENB	START	SRATE1	SRATE0	MLSB	SCKMD	CPOL	CPHA
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
After reset	0	0	0	0	0	0	0	0

Bit 7 **SENB:** SIO function control bit.

0 = Disable SIO function. P5.0~P5.2 are GPIO.

1 = Enable SIO function. P5.0~P5.2 are SIO pins. **SIO pin structure can be push-pull structure and open-drain structure controlled by P1OC register.**

- Bit 6 **START:** SIO progress control bit. 0 = End of transfer. 1 = SIO transmitting.
- Bit [5:4] SRATE1,0: SIO's transfer rate select bit. These 2-bits are workless when SCKMD=1. 00 = fcpu.
 - 01 = fcpu/32
 - 10 = fcpu/16
 - 11 = fcpu/8.
- Bit 3 **MLSB:** MSB/LSB transfer first. 0 = MSB transmit first. 1 = LSB transmit first.
- Bit 2 **SCKMD:** SIO's clock mode select bit. 0 = Internal. (Master mode) 1 = External. (Slave mode)
- Bit 1 **CPOL:** SCK idle status control bit. 0 = SCK idle status is low status. 1 = SCK idle status is high status.
- Bit 0 **CPHA:** The Clock Phase bit controls the phase of the clock on which data is sampled.
 - 0 = Data receive at the first clock phase.
 - 1 = Data receive at the second clock phase.

Because SIO function is shared with Port5 for P5.0 as SCK, P5.1 as SI and P5.2 as SO. The following table shows the Port5[2:0] I/O mode behavior and setting when SIO function enable and disable.

SENB=1 (SI	O Function Enable)						
	(SCKMD=1)	P5.0 will change to Input mode automatically, no matter what P5M					
P5.0/SCK	SIO source = External clock	setting.					
F3.0/3CK	(SCKMD=0)	P5.0 will change to Output mode automatically, no matter what					
	SIO source = Internal clock	P5M setting.					
P5.1/SI	P5.1 must be set as Input mode	e in P5M ,or the SIO function will be abnormal					
P5.2/SO	SIO = Transmitter/Receiver	P5.2 will change to Output mode automatically, no matter what					
P5.2/50		P5M setting.					
SENB=0 (SI	O Function Disable)						
P5.0/P5.1/P	5.2 Port5[2:0] I/O mode are fully c	ontrolled by P5M when SIO function Disable					

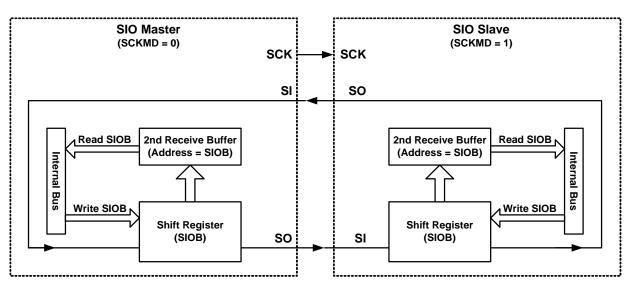

* Note:

- 1. If SCKMD=1 for external clock, the SIO is in SLAVE mode. If SCKMD=0 for internal clock, the SIO is in MASTER mode.
- 2. Don't set SENB and START bits in the same time. That makes the SIO function error.
- 3. SIO pin can be push-pull structure and open-drain structure controlled by P1OC register.

9.4 SIOB DATA BUFFER

0B6H	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
SIOB	SIOB7	SIOB6	SIOB5	SIOB4	SIOB3	SIOB2	SIOB1	SIOB0
Read/Write	R/W							
After reset	0	0	0	0	0	0	0	0

SIOB is the SIO data buffer register. It stores serial I/O transmit and receive data. The system is single-buffered in the transmit direction and double-buffered in the receive direction. This means that bytes to be transmitted cannot be written to the SIOB Data Register before the entire shift cycle is completed. When receiving data, however, a received byte must be read from the SIOB Data Register before the next byte has been completely shifted in. Otherwise, the first byte is lost. Following figure shows a typical SIO transfer between two micro-controllers. Master MCU sends SCK for initial the data transfer. Both master and slave MCU must work in the same clock edge direction, and then both controllers would send and receive data at the same time.

SIO Data Transfer Diagram

9.5 SIOR REGISTER DESCRIPTION

0B5H	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
SIOR	SIOR7	SIOR6	SIOR5	SIOR4	SIOR3	SIOR2	SIOR1	SIOR0
Read/Write	W	W	W	W	W	W	W	W
After reset	0	0	0	0	0	0	0	0

The SIOR is designed for the SIO counter to reload the counted value when end of counting. It is like a post-scaler of SIO clock source and let SIO has more flexible to setting SCK range. Users can set the SIOR value to setup SIO transfer time. To setup SIOR value equation to desire transfer time is as following.

SCK frequency = (SIO rate / (256 - SIOR))/2

SIOR = 256 - (1 / (2 * SCK frequency) * SIO rate)

> Example: Setup the SIO clock to be 5KHz. Fhosc = 16MHz. SIO's rate = Fcpu = Fhosc/16.

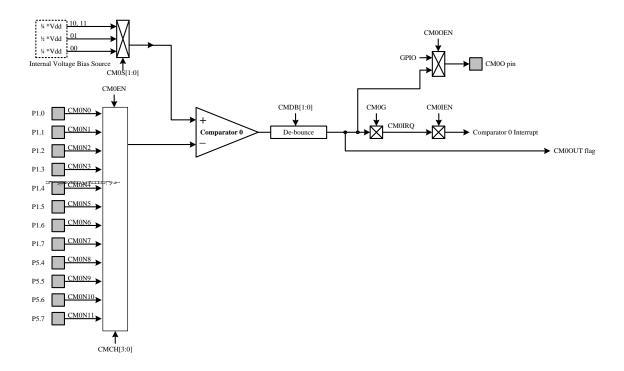

SIOR = 256 - (1/(2*5KHz) * 16MHz/16) = 256 - (0.0001*100000) = 256 - 100 = 156

10.1 OVERVIEW

The analog comparator compares negative input voltage, and then output the result to comparator output terminal. The comparator has multi-input selection for different applications. The comparator negative input terminal is up to 12-channel controlled by CMCH[3:0]. The comparator positive input terminal has three selections controlled by CMOS[1:0] bits. The comparator output terminal connects to external pin CM0O and connects to internal path. There is a programmable direction function to decide comparator trigger edge for indicator function. The comparator has flag indicator, interrupt function and green mode weak-up function for different application.

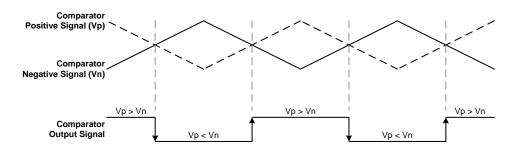

- 12-channel negative input selection.
- Comparator output function.
- Programmable internal reference voltage connected to comparator's positive terminal.
- Programmable trigger direction.
- Interrupt function.
- Green mode wake-up function.

10.2 COMPARATOR OPERATION

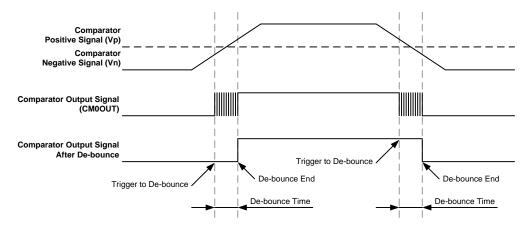

The comparator operation is to compare the voltage between comparator positive input and negative input terminals. When the positive input voltage is greater than the negative input voltage, the comparator output is high status. When the positive input voltage is smaller than the negative input voltage, the comparator output is low status.

The comparator builds in interrupt function. The interrupt function trigger edge is selected by CM0G. The trigger edge supports rising edge (CM0G=0), falling edge (CM0G=1). If the trigger edge condition is found, the CM0IRQ is set as "1". If the comparator interrupt function enables, the system will execute interrupt routine. The CM0IRQ must be cleared by program.

The comparator builds in green mode wake-up function. The comparator green mode wake-up trigger edge is bi-direction. The comparator's wake-up function only supports green mode, not power down mode. If the trigger edge condition (comparator output status exchanging) is found, the system will be wake-up from green mode. If the trigger edge direction is interrupt trigger condition, the CM0IRQ is set as "1". Of course the interrupt routine is executed if the interrupt function enabled. When the wake-up trigger edge direction is equal to interrupt trigger condition, the system will execute interrupt operation after green mode wake-up immediately.

The critical condition is comparator positive voltage equal to comparator negative voltage, and the voltage range is decided comparator offset parameter of input common mode. In the voltage range, the comparator output signal is unstable and keeps oscillating until the differential voltage exits the range. In the condition, the comparator flag (CM0IRQ) latches the first exchanging and issue the status, but the status is a transient, not a stable condition. So the comparator builds in a filter to de-bounce the transient condition. The comparator output signal is through a de-bounce circuit to filter comparator transient status. The de-bounce time is controlled by CMDB[1:0] bits that means the comparator minimum response time is 1*Fcpu, 2*Fcpu, 3*Fcpu or no de-bounce. The de-bounce time depends on the signal slew rate and selected by program.

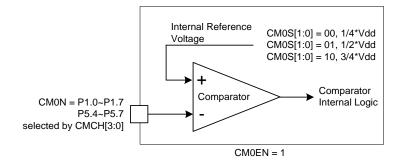

The comparator positive input terminal includes internal reference voltage source. The internal reference voltage source supports three levels which are 1/4*Vdd (CM0S[1:0] = 00), 1/2*Vdd (CM0S[1:0] = 01) and 3/4*Vdd (CM0S[1:0] = 10,11).

The comparator negative input terminal supports maximum 12-channel controlled by CMCH [3:0]. 0000=P1.0. 0001=P1.1. 0010=P1.2. 0011=P1.3. 0100=P1.4. 0101=P1.5. 0110=P1.6. 0111=P1.7. 1000=P5.4. 1001=P5.5. 1010=P5.6. 1011=P5.7. These channels selected is only when the comparator enables (CM0EN=1), the 12-channel analog switch works, or not workable. If one pin is selected to be comparator negative input pin, the pin is switched to input mode and connected to comparator negative input terminal. When the system selects to other pin or comparator disables, the original channel will returns to last GPIO mode automatically.

The comparator output status can output to CM0O pin controlled by CM0OEN bit. When CM0OEN=0, the comparator output pin is GPIO mode. If CM0OEN=1, CM0O pin outputs comparator output status and isolates GPIO mode. The comparator output terminal connects to internal path. The CM0OUT flag is the CM0OUT shows the comparator result immediately, but the CM0IRQ only indicates the event of the comparator result. The comparator output terminal through de-bounce circuit generates the comparator trigger edge controlled by CM0G. The even condition is controlled by register and includes rising edge (CM0OUT changes from low to high), falling edge (CM0OUT changes from high to low) controlled by CM0G bit. The CM0IRQ = 1 condition makes the comparator interrupt service executed when CM0IEN (comparator interrupt control bit) set.

10.3 COMPARATOR CONTROL REGISTER

09CH	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0

Bit [3:2] **CMDB[1:0]:** Comparator output denounce time select bit.

- 00 = 1*Fcpu.
- 01 = 2*Fcpu.
- 10 = 3*Fcpu.
- 11 = No de-bounce.
- Bit 1 **CMOOEN:** Comparator output pin control bit.
 - 0 = Disable. CM0O pin is GPIO mode.
 - 1 = Enable comparator output pin. P0.0 pin exchanges to comparator output pin (CM0O pin), and GPIO function is isolated.
- Bit 0 **CM0G:** Comparator interrupt trigger direction control bit.
 - 0 = Rising edge trigger. comparator internal reference voltage > CM0N.
 - 1 = Falling edge trigger. comparator internal reference voltage < CM0N.

10.4 COMPARATOR APPLICATION NOTICE

The comparator is to compares the positive voltage and negative voltage to output result. The positive used internal reference and negative sources are analog signal. In hardware application circuit, the comparator input pins must be connected a 0.1uF comparator to reduce power noise and make the input signal more stable. The application circuit is as following.

Example: Use comparator 0 to measure the external analog signal. When the analog signal is smaller than 1/2*Vdd, to execute interrupt service routine. In the case, use comparator internal 1/2*Vdd reference voltage to be the comparator positive voltage

In the case, use comparator internal 1/2*Vdd reference voltage to be the comparator positive voltage source. The interrupt trigger condition is comparator output from low to high rising edge.

; The compara	tor 0 initialize.		
	MOV B0MOV	A, #00010000b CM0M, A	; CM0S[1:0]=01b, enable comparator internal 1/2*Vdd ; reference voltage to be comparator positive source. ; CMCH[3:0]=0000b, select comparator negative input pin ; is CM0N0.
	MOV	A, #0000000b	; CM0G=0b, set comparator interrupt request as
	B0MOV	CM0M1, A	; rising edge. ; CMDB[1:0]=00b, no de-bounce.
	BOBSET	FCM0IEN	; CM0IEN=1, enable comparator 0 interrupt function.
	B0BCLR	FCM0IRQ	; CM0IRQ=0, clear comparator 0 interrupt request flag.
	BOBSET	FCM0EN	; Enable comparator 0.
Main:			; Main loop.
	JMP	MAIN	

; Interrupt service routine. Jump from interrupt vector (ORG 8).

ISR:

ISR_EXIT:

PUSH B0BTS1 JMP	FCM0IRQ ISR_EXIT	; Save ACC and PFLAG. ; Check comparator 0 interrupt request flag. ; No interrupt request, exit interrupt service routine.
B0BCLR 	FCM0IRQ	; Clear comparator 0 interrupt request flag. ; Execute comparator 0 interrupt service routine.
JMP	ISR_EXIT	; End of comparator 0 interrupt service routine.
POP RETI		; Exit interrupt service routine. ; Reload ACC and PFLAG. ; Return to main loop.

11 MAIN SERIAL PORT (MSP)

11.1 OVERVIEW

The MSP (Main Serial Port) is a serial communication interface for data exchanging from one MCU to one MCU or other hardware peripherals. These peripheral devices may be serial EEPROM, A/D converters, Display device, etc. The MSP module only can operate in slave mode:

• Slave mode (with general address call).

The MSP features include the following:

- 2-wire synchronous data transfer/receiver.
- Slave (SCL is clock input) operation.
- SCL, SDA are programmable open-drain output pin for multiplex salve devices application.
- Support 400K clock rate @ Fcpu=4MIPs.
- End-of-Transfer/Receiver interrupt.

11.2 MSP STATUS REGISTER

090H	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
MSPSTAT	-	CKE	D_A	Р	S	RED_WRT	-	BF
Read/Write	-	R/W	R	R	R	R	-	R
After reset	-	0	0	0	0	0	-	0

Bit 6 **CKE:** Slave Clock Edge Control bit

In Slave Mode: Receive Address or Data byte

0= Latch Data on SCL Rising Edge. (Default)

1= Latch Data on SCL Falling Edge.

* Note:

- 1. In Slave Transmit mode, Address Received depended on CKE setting. Data Transfer on SCL Falling Edge.
- 2. In Slave Receiver mode, Address and Data Received depended on CKE setting.
- Bit 5 **D_A:** Data/Address_ bit

0=Indicates the last byte received or transmitted was address. 1= Indicates the last byte received or transmitted was data.

Bit 4 P: Stop bit

0 = Stop bit was not detected.

1 = Indicates that a stop bit has been detected last.

* Note: It will be cleared when Start bit was detected.

- Bit 3 Start bit.
 - 0 = Start bit was not detected.
 - 1 = Indicates that a start bit has been detected last
- Note: It will be cleared when STOP bit was detected.

Bit 2 **RED_WRT:** Read/Write bit information.

This bit holds the R/W bit information following the last address match. This bit is only valid from the address match to the next start bit, stop bit, or not ACK bit.

- In slave mode:
- 0 = Write.
- 1 = Read.
- Bit 0 BF: Buffer Full Status bit
 - **Receive**
 - 1 = Receive complete, MSPBUF is full.
 - 0 = Receive not complete, MSPBUF is empty.
 - <u>Transmit</u>
 - 1 = Data Transmit in progress (does not include the ACK and stop bits), MSPBUF is full.
 - 0 = Data Transmit complete (does not include the ACK and stop bits), MSPBUF is empty.

11.3 MSP MODE REGISTER1

091H	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
MSPM1	WCOL	MSPOV	MSPENB	CKP	SLRXCKP	MSPWK	GCEN	-
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	-
After reset	0	0	0	0	0	0	0	-

Bit 7 WCOL: Write Collision Detect bit

- Slave Mode:
- 0 = No collision

1 = The MSPBUF register is written while it is still transmitting the previous word (must be cleared in software)

- Bit 6 MSPOV: Receive Overflow Indicator bit
 - 0 = No overflow.

1 = A byte is received while the MSPBUF register is still holding the previous byte. MSPOV is a "don't care" in transmit mode. MSPOV must be cleared in software in either mode. (must be cleared in software)

- Bit 5 **MSPENB:** MSP Communication Enable.
 - 0 = Disables serial port and configures these pins as I/O port pins
 - 1 = Enables serial port and configures SCL, SDA as the source of the serial port pins

* Note: MSP status register will be clear after MSP Disable. So, user should setting MSP register again before MSP Enable.

- Ex: B0BCLR FMSPENB CALL MSP_init_setting
 - BOBSET FMSPENB

 Bit 4
 CKP: SCL Clock Priority Control bit

 In MSP Slave mode
 0 = Hold SCL keeping Low. (Ensure data setup time and Slave device ready.)

 1 = Release SCL Clock
 (Slave Transistor mode CKP function always enables, Slave Receiver CPK function control by SLRXCKP)

Bit 3 SLRXCKP: Slave Receiver mode SCL Clock Priority Control bit

- In MSP Slave Receiver mode.
- 0 = Disable CKP function.
- 1 = Enable CKP function.
- In MSP Slave and Slave Transistor mode Unused.

Bit 2 **MSPWK:** MSP Wake-up indication bit 0 = MCU NOT wake-up by MSP. 1 = MCU wake-up by MSP

Note: Clear MSPWK before entering Power down mode for indication the wake-up source from MSP or not

GCEN: General Call Enable bit (In Slave mode only) Bit 1

- 0 = General call address disabled
- 1 = Enable interrupt when a general call address (0000h) is received.

11.4 MSP MSPBUF REGISTER

MSPBUF initial value = 0000 0000

092H	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
MSPBUF	MSPBUF7	MSPBUF6	MSPBUF5	MSPBUF4	MSPBUF3	MSPBUF2	MSPBUF1	MSPBUF0
Read/Write	R/W							
After reset	0	0	0	0	0	0	0	0

11.5 MSP MSPADR REGISTER

MSPADR init	tial value = 0	000 0000						
093H	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
MSPADR	MSPADR7	MSPADR6	MSPADR5	MSPADR4	MSPADR3	MSPADR2	MSPADR1	MSPADR0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
After reset	0	0	0	0	0	0	0	0

.

11.6 SLAVE MODE OPERATION

When an address is matched or data transfer after and address match is received, the hardware automatically will generate the acknowledge (ACK_) signal, and load MSPBUF (MSP buffer register) with the received data from MSPSR.

There are some conditions that will cause MSP function will not reply ACK_ signal:

- Data Buffer already full: BF=1 (MSPSTAT bit 0), when another transfer was received.
- Data Overflow: MSPOV=1 (MSPM1 bit 6), when another transfer was received

When BF=1, means MSPBUF data is still not read by MCU, so MSPSR will not load data into MSPBUF, but MSPIRQ and MSPOV bit will still set to 1. BF bit will be clear automatically when reading MSPBUF register. MSPOV bit must be clear through by Software.

11.6.1 ADDRESSING

When MSP Slave function has been enabled, it will wait a START signal occur. Following the START signal, 8-bit address will shift into the MSPSR register. The data of MSPSR[7:1] is compare with MSPADDR register on the falling edge of eight SCL pulse. If the address are the same, the BF and SSPOV bit are both clear, the following event occur:

- 1. MSPSR register is loaded into MSPBUF on the falling edge of eight SCL pulse.
- 2. Buffer full bit (BF) is set to 1, on the falling edge of eight SCL pulse.
- An ACK signal is generated. 3
- MSP interrupt request MSPIRQ is set on the falling edge of ninth SCL pulse. 4

	vhen Data is ceived	MSPSR→ MSPBUF	Reply an ACK_ signal	Set MSPIRQ
BF	MSPOV			
0	0	Yes	Yes	Yes
*0	*1	Yes	No	Yes
1	0	No	No	Yes
1	1	No	No	Yes

Data Received Action Table

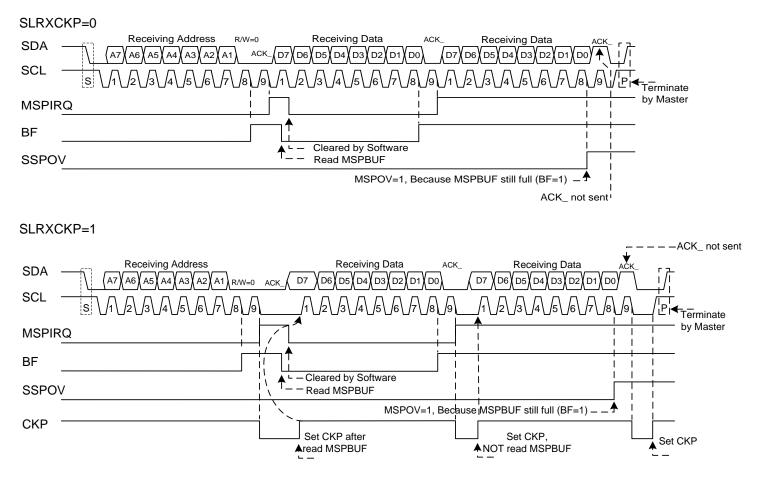

Note: BF=0, MSPOV=1 shows the software is not set properly to clear Overflow register.

11.6.2 SLAVE RECEIVING

When the R/W bit of address byte =0 and address is matched, the RED_WRT bit of MSPSTAT is cleared. The address will be load into MSPBUF. After reply an ACK_ signal, MSP will receive data every 8 clock. The CKP function enable or disable (Default) is controlled by SLRXCKP bit and data latch edge -Rising edge (Default) or Falling edge is controlled by CPE bit.

When overflow occur, no acknowledge signal replied which either BF=1 or MSPOV=1. MSP interrupt is generated in every data transfer. The MSPIRQ bit must be clear by software.

Following is the Slave Receiving Diagram

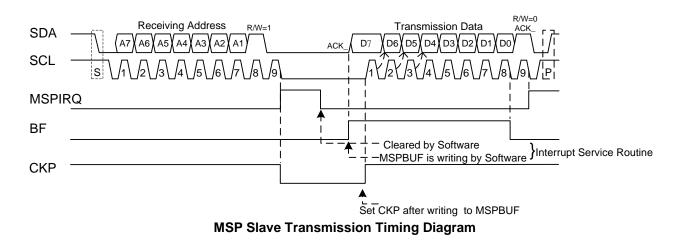

11.6.3 SLAVE TRANSMISSION

After address match, the following R/W bit is set, MSPSTAT bit 2 RED_WRT will be set. The received address will be load to MSPBUF and ACK_ will be sent at ninth clock then SCL will be hold low. Transmission data will be load into MSPBUF which also load to MSPSR register. The Master should monitor SCL pin signal. The slave device may hold on the master by keep CKP low. When set. After load MSPBUF, set CKP bit, MSPBUF data will shift out on the falling edge on SCL signal. This will ensure the SDA signal is valid on the SCL high duty.

An MSP interrupt is generated on every byte transmission. The MSPIRQ will be set on the ninth clock of SCL. Clear MSPIRQ by software. MSPSTAT register can monitor the status of data transmission.

In Slave transmission mode, an ACK_ signal from master-receiver is latched on rising edge of ninth clock of SCL. If ACK_ = high, transmission is complete. Slave device will reset logic and waiting another START signal. If ACK_= low, slave must load MSPBUF which also MSPSR, and set CKP=1 to start data transmission again.

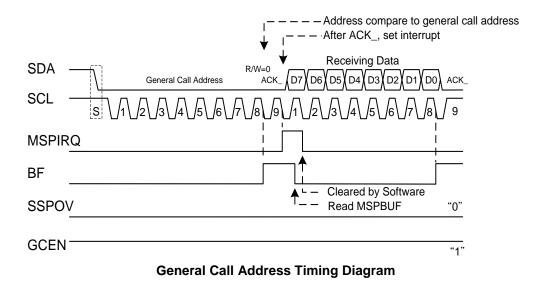

11.6.4 GENERAL CALL ADDRESS

In MSP bus, the first 7-bit is the Slave address. Only the address match MSPADR the Slave will response an ACK_. The exception is the general call address which can address all slave devices. When this address occur, all devices should response an acknowledge.

The general call address is a special address which is reserved as all "0" of 7-bit address. The general call address function is control by GCEN bit. Set this bit will enable general call address and clear it will disable. When GECN=1, following a START signal, 8-bit address will shift into MSPSR and the address is compared with MSPADR and also the general call address which fixed by hardware.

If the genera call address matches, the MSPSR data is transferred into MSPBUF, the BF flag bit is set, and in the falling edge of the ninth clock (ACK_) MSPIRQ flag set for interrupt request. In the interrupt service routine, reading MSPBUF can check if the address is the general call address or device specific.

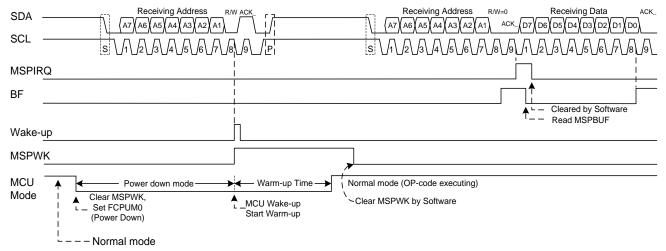

11.6.5 SLAVE WAKE UP

When MCU enter Power down mode, if MSPENB bit is still set, MCU can wake-up by matched device address. The address of MSP bus following START bit, 8-byte address will shift into MSPSR, if address matched, an NOT Acknowledge will response on the ninth clock of SCL and MCU will be wake-up, MSPWKset and start wake-up procedure but MSPIRQ will not set and MSPSR data will not load to MSPUBF. After MCU finish wake-up procedure, MSP will be in idle status and waiting master's START signal. Control register BF, MSPIRQ, MSPOV and MSPBUF will be the same status/data before power down.

If address not matches, a NOT acknowledge is still sent on the ninth clock of SCL, but MCU will be NOT wake-up and still keep in power down mode.

SDA	Receiving Address R/W ACK_
	"0"
BF	"0"
Wake-up	"0"
MSPWK	"0"
MCU Mode L Set FCPUM (Power Down	0 n)

MSP Wake-up Timing Diagram: Address NOT Matched

MSP Wake-up Timing Diagram: Address Matched

After into power down mode, we need to disable MSP and then enable MSP to reset MSP function and re-write the I2C slave address.

 \triangleright

Example:		
BOBSET	FCPUM0	
B0BCLR	FMSPENB	
NOP		
BOBSET	FMSPENB	
MOV	A, #0xnn	
B0MOV	MSPADR, A	; Re-write the I2C slave address again.

* Note:

- 1. MSP function only can work on Normal mode, when wake-up from power down mode, MCU must operate in Normal mode before Master sent START signal.
- 2. In MSP wake-up, if the address not matches, MCU will keep in power down mode.
- 3. Clear MSPWK before enter power down mode by Software for wake-up indication.

13.3 CHARACTERISTIC GRAPHS

The Graphs in this section are for design guidance, not tested or guaranteed. In some graphs, the data presented are outside specified operating range. This is for information only and devices are guaranteed to operate properly only within the specified range (-40 $^{\circ}$ C ~+85 $^{\circ}$ C curves are for design reference).

14 DEVELOPMENT TOOL

SONIX provides ICE (in circuit emulation), IDE (Integrated Development Environment) and EV- KIT for SN8P2523 development. ICE and EV-KIT are external hardware devices, and IDE is a friendly user interface for firmware development and emulation. These development tools' version is as following.

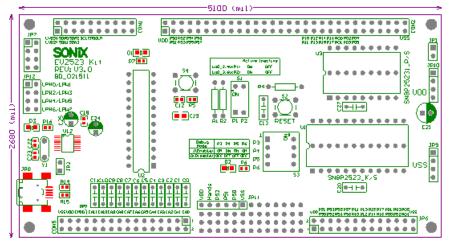

- ICE: SN8ICE2K Plus II. (Please install 16MHz crystal in ICE to implement IHRC emulation.).
- ICE emulation speed maximum: 8 MIPS @ 5V (e.g. 16Mhz crystal, Fcpu = Fosc/2).
- EV-KIT: EV2523 Kit REV: V3.0.
- IDE: SONiX IDE M2IDE_V129 or greater.
- Writer: MPIII writer.
- Writer transition board: SN8P2523

14.1 SN8P2523 EV-KIT

SN8P2523 EV- KIT includes ICE interface, GPIO interface and EV-chip, PWM module.

EV-chip module: Emulate 12 channel comparator function. **PWM module:** Emulate 8 channel pwm function.

SN8P2523 EV- KIT PCB Outline:

- CON1, CON2: ICE interface connected to SN8ICE2K Plus 2.
- JP6: GPIO connector.
- U2: SN8P2523 EV-chip for comparator emulation.
- U1: SN8P2523 SKDIP/SOP socket for connecting to user's target board.
- U3: SN8P25231 PDIP/SOP socket for connecting to user's target board.
- S1: LVD24 and LVD36 emulating switch.
- C0~C11: 12 channel comparator capacitors.
- CON5 (CA0~CA11): 12 channel comparator connectors.
- JP12: 8 channel PWM connectors.

14.2 ICE and EV-KIT APPLICATION NOTIC

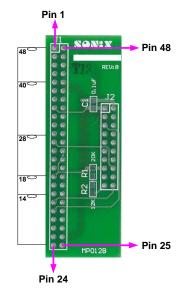

- 1. SN8P2523 EV- KIT includes comparator emulation module and 8-pwm module.
- 2. The SN8P2523 EV-chip programmed emulating code to emulate comparator function.
- 3. For comparator emulation, input comparator signals are from CA0~CA11 pins.
- 4. For 8-PWM emulation, output pins are from connector JP12 (LPW0~LPW7).
- 5. For the GPIO function emulation is from connector JP6.
- 6. SN8P2523 EV- KIT power switch table as follows:

	JP1	JP2	JP10
ICE Power	SHORT	OPEN	OPEN
External Power	OPEN	OPEN	SHORT
USB Power	OPEN	SHORT	OPEN

16 Marking Definition

16.1 INTRODUCTION

There are many different types in Sonix 8-bit MCU production line. This note listed the production definition of all 8-bit MCU for order or obtain information. This definition is only for Blank OTP MCU.

16.2 MARKING INDETIFICATION SYSTEM

16.3 MARKING EXAMPLE

Wafer, Dice:

Name	ROM Type	Device	Package	Temperature	Material
